- 6 MEDAN

The Grocery Store Example/1

- A **grocery chain** with 500 stores spread over a five-state area.
 - Each of the stores is a typical modern supermarket with a full complement of departments including grocery, frozen foods, dairy, meat, bakery, hard goods, liquor, and drugs.
 - Each store has roughly 60,000 individual products on its shelves.
- The individual products are called **stock keeping units (SKUs)**.
- About 40,000 of the SKUs come from **outside manufacturers** and have bar codes imprinted on the product package.
 - These bar codes are called **universal product codes (UPCs)**.
 - UPCs are at the same grain as individual SKUs.
 - Each different **package variation of a product** has a separate UPC and hence is a separate SKU.
- The remaining 20,000 SKUs come from **departments** like meat or bakery departments and do not have nationally recognized UPC codes.
 - The grocery store assigns SKU numbers to these products by sticking scanner labels on the items.
 - Although the bar codes are not UPCs they are certainly SKU numbers.

The Grocery Store Example/2

- Data is collected at several places in a grocery store.
 - Some of the most useful data is collected at the cash registers as customers purchase products.
 - Our modern grocery store scans the bar codes directly into the point-of-sale (POS) system.
 - The POS system is at the front door of the grocery store where customer takeaway is measured.
 - The back door, where vendors make deliveries, is another interesting data-collection point.

The Grocery Store Example/3

- At the grocery store, management is concerned with the logistics of ordering, stocking the shelves, and selling the products **while maximizing the profit** at each store.
- The **profit** ultimately comes from
 - **charging as much as possible** for each product,
 - **lowering costs** for product acquisition and overhead, and
 - at the same time **attracting as many customers** as possible.
- The most **significant decisions** have to do with **pricing** and **promotions**.
 - Both store management and headquarters marketing **spend a great deal of time** tinkering with pricing and running promotions.
 - **Promotions** in a grocery store include temporary price reductions, ads in newspapers and newspaper inserts, displays in the grocery store, and coupons.

Simplified DM Design Process (Kimball and Ross)

- A somehow **simplified DM design process** consists of the following 4 steps:
 - 1 Choose the **business process(es)** to model
 - e.g., Sales,
 - 2 Choose the **granularity** of the business process
 - e.g., Items by Store by Promotion by Day.
 - Low granularity is needed.
 - Are individual transactions necessary/feasible?
 - 3 Choose the **dimensions**
 - Time, Store, . . .
 - 4 Choose the **measures**
 - Dollar_sales, unit_sales, dollar_cost, customer_count

Step 1: Choose the Business Process

- A **business process** is an activity in the organization that typically is supported by a source data management system
 - raw material purchasing, orders, shipments, invoicing, inventory, bank transfers, patient transfers, . . .
- Business processes are not necessarily limited to a single department
 - e.g., sales and marketing departments might be interested in the orders
- **Focusing on the business process** rather than the department avoids duplication of work and keeps data more consistent
- The **first dimensional model** built should be the one with the **most impact**
- It should answer the **most pressing business questions** and be readily accessible for data extraction

Step 1: Choose the Business Process – Example

- Management wants to better understand **customer purchases** as captured by the POS system.
- Business process: **POS retail sales**
- Allows us to analyze:
 - What products are selling?
 - In which stores?
 - On what days?
 - Under what promotional conditions?
 - etc.

Step 2: Choose the Grain of the Business Process

- Preferably develop dimensional models for the **most atomic information** captured by a business process
 - Not because queries report individual rows, but queries need to cut through the details in very precise ways
- The more detailed/atomic data is, the more things we know
- Atomic data provides **maximum analytic flexibility**
- Can be constrained and rolled up in every possible way
- It is always possible to declare higher-level grains by aggregation of atomic data; the opposite is not true
- Less granular model is vulnerable to **unexpected requests** for more details
- Example **grain declarations**
 - Individual line item on a customer's sales ticket as measured by a scanner
 - An individual boarding pass of a flight
 - A monthly snapshot for each bank account

Step 2: Choose the Grain of the Business Process – Example

- Individual line item on a POS transaction is the most detailed data, and we choose this as grain (→ **event fact**)
- Allows a very detailed analysis of sales
 - Difference in sales on Monday vs. Sunday
 - Is it worthwhile to stock so many individual sizes of certain brands?
 - How many shoppers took advantage of the 50-cents-off promotion on shampoo?
 - Impact in terms of increasing sales when a competitive diet soda product was promoted
 - etc.
- Note that none of these queries calls for data from a specific transaction, but require detailed ways to slice data
 - Could not be answered if only aggregated values would be stored, e.g., daily summaries

Step 3: Choose the Dimensions

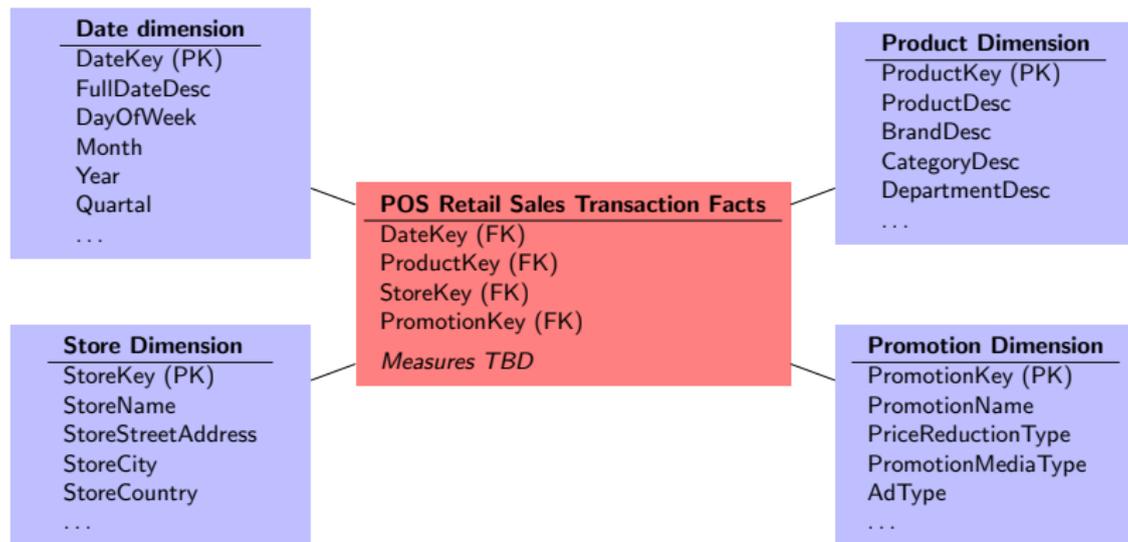

- Dimensions can be derived by answering the question *“How do business people describe the data resulting from the business processes?”*
- **“Decorate” fact tables** with dimensions representing all possible descriptions of the facts/measures
- A clear grain statement helps to identify the dimensions
- Sometimes a revision of step 2 is required

Step 3: Choose the Dimensions – Example/1

- The **Date** dimension
 - Explicit date dimension is needed (events, holidays, ...)
- The **Product** dimension
 - Hierarchy allows drill-down/roll-up through category, brand, department, etc.
 - Many descriptive attributes (often more than 50)
- The **Store** dimension
 - Primary geographic dimension to specify location of the store
 - Many descriptive attributes
- The **Promotion** dimension
 - Used to see if promotions work and are profitable
 - Ads, price reductions, end-of-sale displays, coupons
 - Highly correlated (only 5000 combinations)

Step 3: Choose the Dimensions – Example/2

- Preliminary version of grocery store schema

Step 4: Choose the Measures

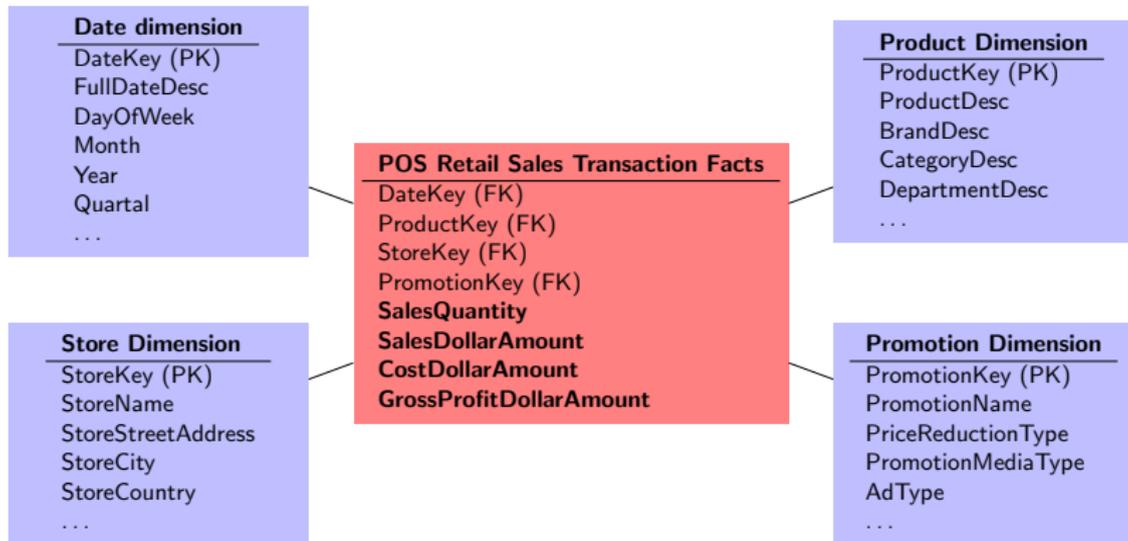

- Identify the **business performance measures** for the selected processes
- Determined by answering “*What are we measuring?*”
- Measures are determined by the grain declaration
- Revision of the grain might be required

Step 4: Choose the Measures – Example

- Sales quantity
- Sales dollar amount
- Cost dollar amount
- Gross profit
 - Equals to sales dollar – cost dollar
 - Explicit storage avoids user errors

- All measures are additive
- Facts are classified as event facts since each POS transaction is stored (most detailed level)

MD Schema of the Grocery Store Example

Outline

- 1 The Grocery Store Example
- 2 More about Multidimensional Modeling**
- 3 Inventory Management Example
- 4 Order Management
- 5 OncoNet
- 6 MEDAN

Database Sizing

- Time dimension: 2 years = 730 days
- Store dimension: 300 stores reporting each day
- Product dimension: 30,000 products, only 3,000 sell per day
- Promotion dimension: 5,000 combinations, but a product only appears in one combination per day
- Number of fact records: $730 \times 300 \times 3,000 \times 1 = 657,000,000$
- Number of fields: 4 key + 4 measures = 8 fields
- Total DB size: $657,000,000 \times 8 \text{ fields} \times 4 \text{ bytes} = 21 \text{ GB}$
- **Small** database by today's standards!

Date Dimension

- **Date dimension** is present in **all DWs**
- Can be created in advance
- **“Meaningful”** values are important for report generation, etc.
 - e.g., Holiday/Nonholiday vs. Yes/No
- Time-of-day a separate dimension
 - Separation keeps both dimensions small
- Date dimension vs. SQL date type
 - Many date attributes are not supported in SQL, e.g., fiscal month
 - Business user is not versed in SQL
- Date dimension is relatively small
 - 10 years = 3,650 rows

Product Dimension

- Description of the products
- >50 attributes is typical for Product dimension
- Concept hierarchy
 - SKU → Brand → Category → Department
 - Many repetitions, but space of dimensions is not critical

Product Dimension

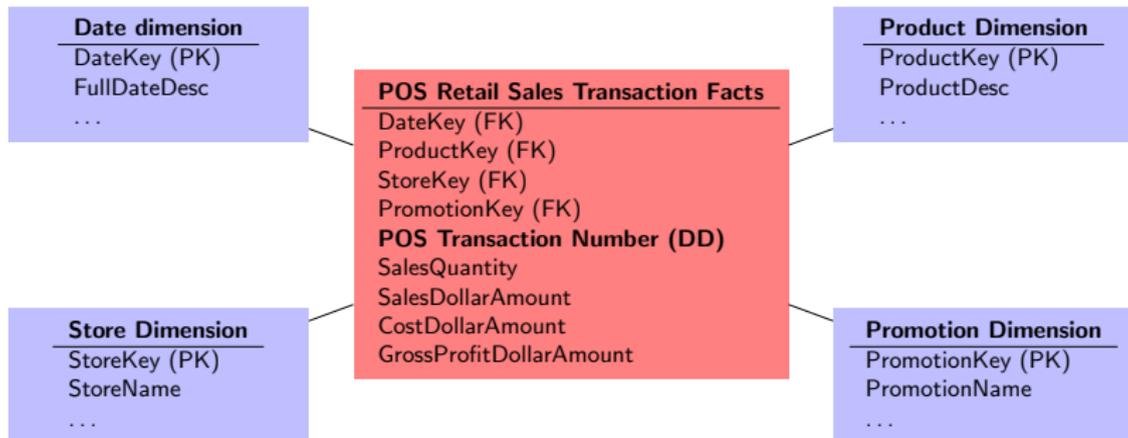

Product Key (PK)
 Product Description
 SKU Number
 Brand Description
 Category Description
 Department Description
 Package Type Description
 Package Size
 Fat Content
 Diet Type
 Weight
 Weight Units of Measure
 ...

Instance of Product dimension table

| 5 | Diet Lovers Vanilla 2 Gallon | Coldpack | Frozen Desserts | Frozen Foods | |
| 6 | Light and Creamy Butter Pecan 1 Pint | Freshlike | Frozen Desserts | Frozen Foods | |

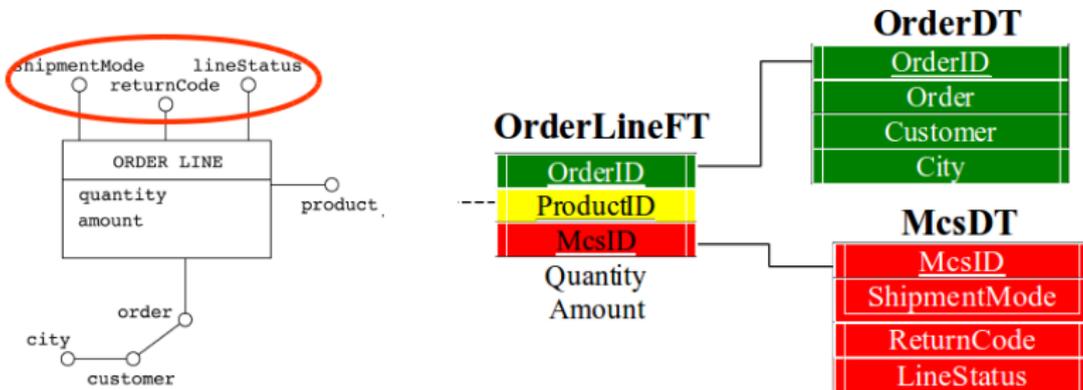

Degenerate Dimensions

- **Degenerate dimensions** are “empty”
 - i.e., dimensions with a “hierarchy” of only one attribute
 - Values are directly stored in **fact table**, no dimension table is needed
- Examples are operational control numbers, e.g., order #, invoice #, POS transaction #, etc.
- Useful to serve as part of primary key in fact table or for grouping
 - e.g, grouping by POS transaction number to retrieve all products purchased in a single transaction

Junk Dimensions

- **Junk dimension:** a dimension table that stores several degenerate dimensions
 - Within a junk dimension there is no functional dependency (hierarchy)
 - Only feasible if the number of distinct values for the attributes is small
- **Example:** 3 generate dimensions combined in a single junk dimension

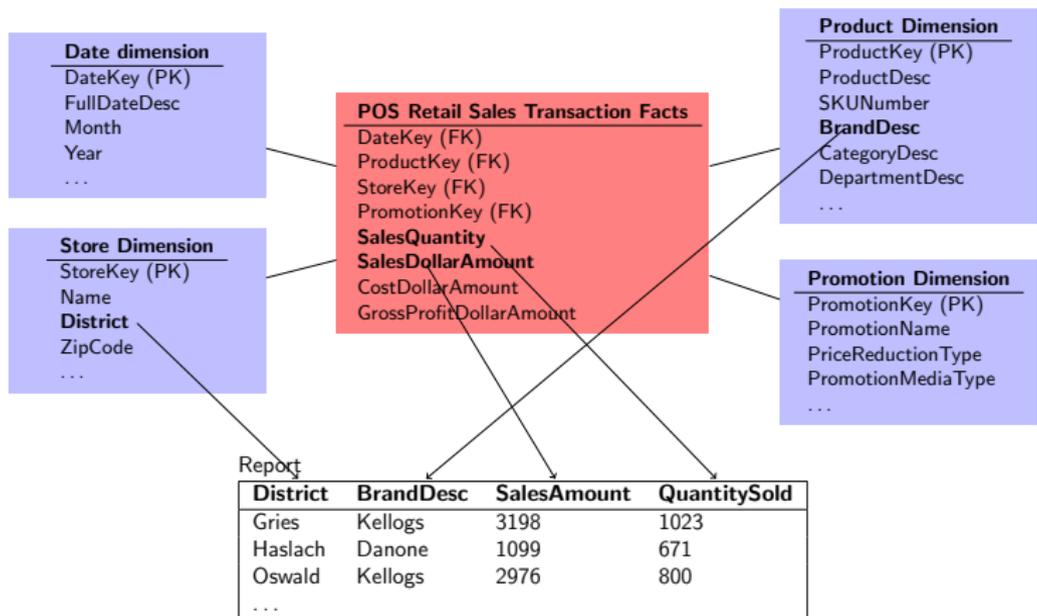

How Many Dimensions?

- Dimensions are important to provide detailed information for the analysis!
- But, **too many** dimensions is **bad!**
 - A sign that dimensions are not independent, and hence should be combined
 - Significantly increases space requirements of fact table
 - Size of dimension table is not a problem
 - 15 dimensions should normally be enough

Working with a Dimensional Model/1

- Each dimension attribute is a **rich source** for constructing row headers
- A common activity is to **drag and drop dimensional attributes** and measures into a simple report (+ specification of aggregate functions for measures)

Working with a Dimensional Model/2

- **Drilling down** is adding row headers from a dimension
- **Rolling up** is removing row headers

| Dept desc | Sales Dollar Amount | Sales Quantity |
|--------------|---------------------|----------------|
| Bakery | \$12.331 | 5088 |
| Frozen Foods | \$31.776 | 15.565 |

Roll up on

...

Surrogate Keys

- **Surrogate keys** are integers that are assigned sequentially in a dimension table, e.g., 1, 2, 3, ...
- Should be used instead of natural operational production codes
- Many advantages over operational codes.
 - Make the DW independent from operational changes
 - e.g., re-use of old operational keys after some time
 - Avoid key overlap problem when consolidating data
 - Dimension keys should not contain “intelligence”
 - Should be stored explicitly as additional attribute
 - Performance: Small integer vs. long alpha-numeric code
 - Results in smaller fact tables
 - 1 Byte in a 1 billion fact table translates into 1 GB disk space

Outline

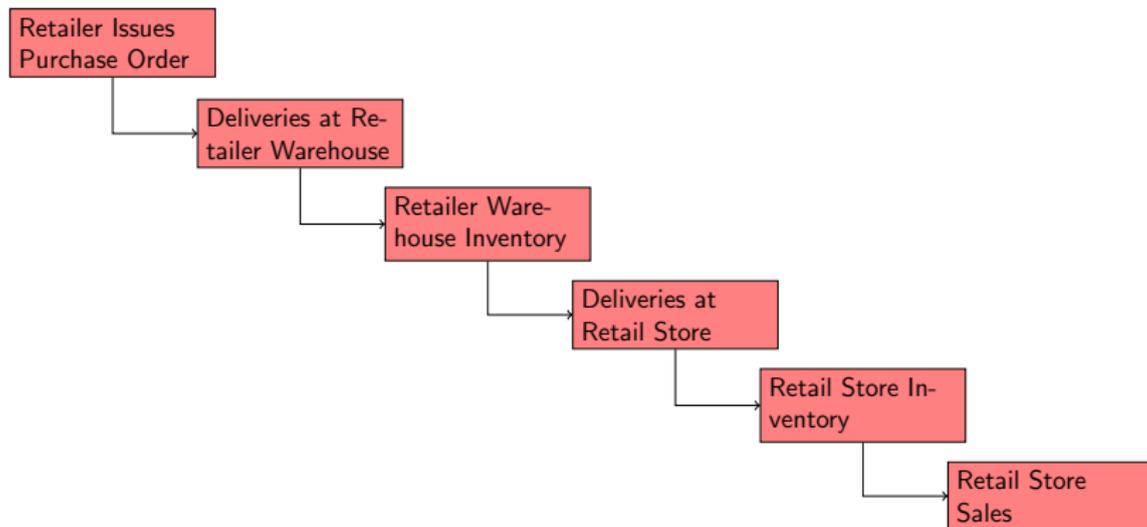

- 1 The Grocery Store Example
- 2 More about Multidimensional Modeling
- 3 Inventory Management Example**
- 4 Order Management
- 5 OncoNet
- 6 MEDAN

Inventory Management

- Consider a large grocery chain with a central warehouse and several retail stores
- Advanced retail business requires inventory information
 - Making sure the right product is in the right store at the right time minimizes out-of-stocks and reduces overall inventory carrying costs
 - The retailer needs the ability to analyze daily quantity-onhand inventory levels by product and store
- Design dimensional models that support the analysis of inventories for retail businesses (grocery stores)

The Value Chain

- The **value chain** identifies the natural, logical flow of an organization's primary activities
- Provides useful information for the **identification of business processes**
- Operational systems provide snapshots at each step with interesting **data** and **performance metrics**

Inventory Models

- 3 different inventory models
 - Model 1: Inventory periodic snapshot model
 - Model 2: Inventory transactions model
 - Model 3: Inventory accumulating snapshot model

Inventory Periodic Snapshot Model/1

- **Model 1: Inventory Periodic Snapshot:** Every day (or at some other regular time interval) the inventory levels of each product is measured and stored as a new row in the fact table
- **Example:** Inventory of retail store
 - Business process: Analysis of retail store inventory
 - Granularity: Daily inventory by product at each individual store
 - Dimensions: Date, product, and store
 - Facts/measures: Quantity on hand

Inventory Periodic Snapshot Model/2

- Inventory generates **dense snapshot tables** (i.e., entry for each product)
 - In contrast, POS Retail Sales table was **sparse**
- Hence, inventory fact table is growing fast!
 - 60.000 products \times 100 stores = 6 Mio. rows each time
 - With a row width of 14 bytes, this is 84 MB each time
 - 1 year of daily snapshots would be 30 GB
- Reduce **snapshot frequencies** over time
 - Last 60 days of inventory at daily level
 - Weekly snapshots for older data
 - Instead of 1.095 snapshots in 3 years, only 208 snapshots would be required

Inventory Periodic Snapshot Model/3

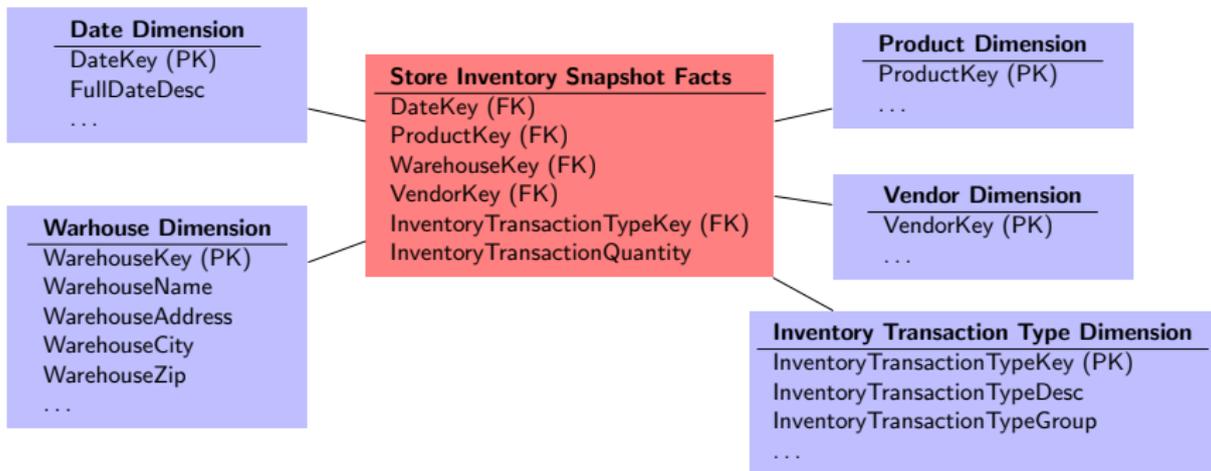

- The quantity on hand is a **semi-additive measure**
 - Can be summarized across products and stores, but not across time
 - Different in POS Retail Sales table: Sold entities are counted only once
- All measures that record a **static level** (inventory, financial account balance, measures of intensity, e.g., temperature) are inherently **non-additive across time** and possibly other dimensions
 - Can be aggregated along time dimension by averaging
- A note about SQL AVG function:
 - Cannot be used to compute the average over time, since it averages over the number of rows
 - Avg inventory over a cluster of 3 products in 4 stores across 7 days would divide the summed value by 84

Inventory Transactions Model/1

- **Model 2: Inventory Transactions:** Every transaction that affects the inventory is recorded
- **Example:** Inventory transactions in the store chain
 - Receive product
 - Place product in to inspection hold
 - Release product from inspection hold
 - Return product to vendor due to inspection failure
 - Place product in bin
 - Authorize product for sale
 - Pick product for shipment
 - Ship product to customer
 - Receive product form customer
 - Return product to inventory from customer return
 - Remove product from inventory

Inventory Transactions Model/2

- Star schema of the inventory transaction model

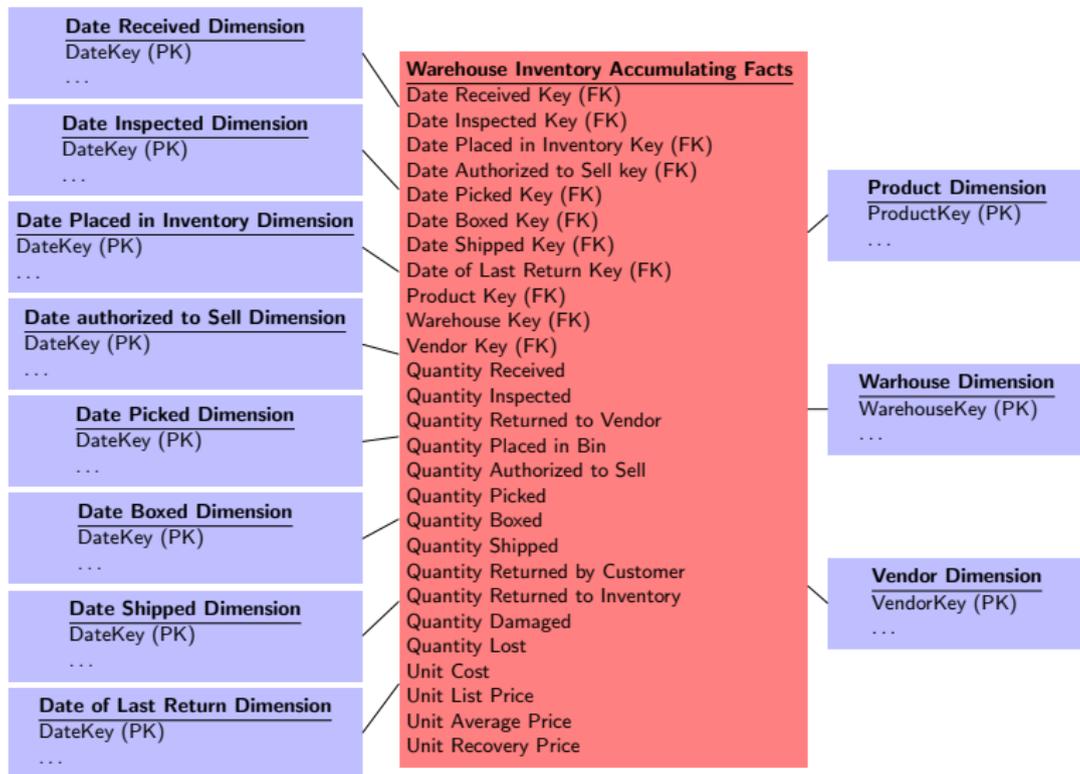

- Contains most detailed information, e.g.,
 - How many shipments from a given vendor?
 - On which products more than one round of inspection?
- Reconstruction of exact inventory numbers is possible, but not practical!
 - Used in combination with other fact table

Inventory Accumulative Snapshot Model/1

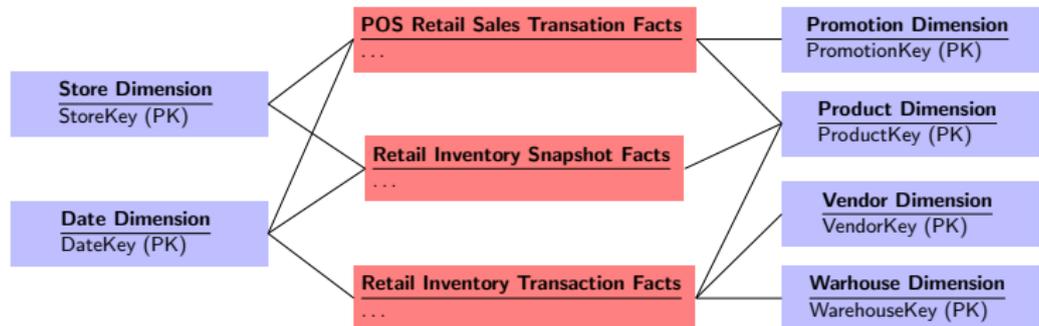

- **Model 3: Inventory Accumulating Snapshot:** One row in the fact table for each shipment of a particular product to the warehouse
- Assumption that the inventory goes through a series of events, e.g., receiving, inspection, bin placement, authorization to sell, picking, boxing, and shipping.
- A row tracks the disposition of a shipment through these events in the warehouse.
- Row is updated as the shipment moves through the warehouse until it leaves the warehouse.
- Characterized by many date dimensions and many updates.

Inventory Accumulative Snapshot Model/2

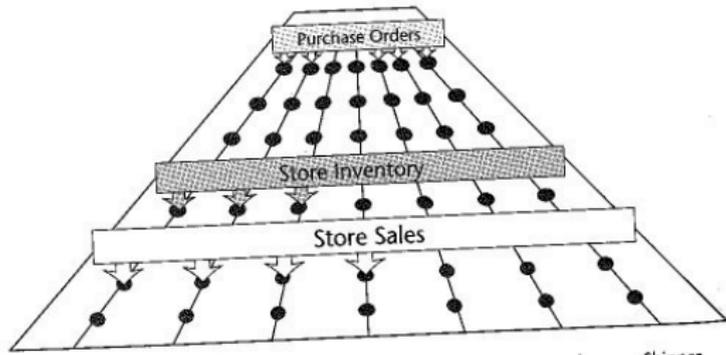

Value Chain Integration and Shared Dimensions

- **Integration across the value chain** is important for the analysis
 - Allows analysis across the business to better evaluate the overall performance (not just at the individual department level)
 - End-to-end perspective high-level management to customer
- This requires the integration and consistent handling/use of data
- **Solution:** Individual fact tables for processes + shared dimensions
- **Shared dimensions** are used by different data marts

Data Warehouse Bus Architecture

- **Data Warehouse Bus Architecture** is a standard bus interface that supports the incremental development of a DW
- Based on **conformed (similar) dimensions** that are **shared** by the DMs
- Useful tool for the design process as it breaks down the process into small chunks (DMs)
- DMs can be realized at different times and by different groups

Data Warehouse Bus Matrix/1

- **Data Warehouse Bus Matrix** is a way to document the bus architecture
 - Rows represent business processes (translate into DMs)
 - Columns represent a suite of standardized, common and shared dimensions

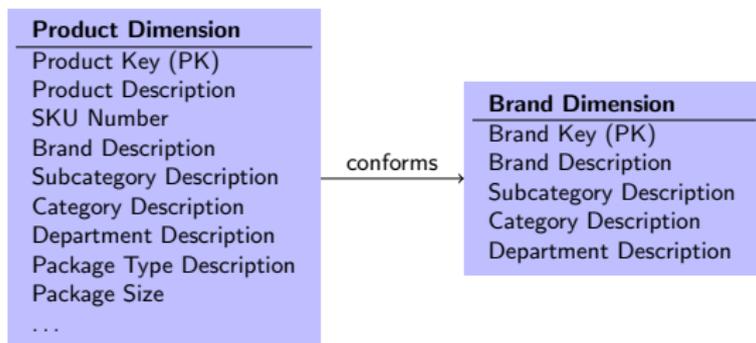

| Business Processes | Shared Dimensions | | | | | | | |
|----------------------|-------------------|---------|-------|-----------|-----------|--------|----------|---------|
| | Date | Product | Store | Promotion | Warehouse | Vendor | Contract | Shipper |
| Retail Sales | X | X | X | X | | | | |
| Retail Inventory | X | X | X | | | | | |
| Retail Deliveries | X | X | X | | | | | |
| Warehouse Inventory | X | X | | | X | X | | |
| Warehouse Deliveries | X | X | | | X | X | | |
| Purchase Orders | X | X | | | X | X | X | X |

Data Warehouse Bus Matrix/2

- Creating the DW bus matrix is one of the most important up-front deliverables of a DW implementation
- Create a comprehensive list of dimensions before filling in the matrix
- The rows provide a concise overview about the dimensionality of the individual DMs
- The columns show the interaction between the DMs and the common/shared dimensions

Conformed Dimensions

- **Conformed Dimensions** are either **identical** or **strict mathematical subsets** of the most granular, detailed dimension
- **Roll-up dimensions** conform to the base-level dimension
- **Example:** The sales process captures data at the product level, while the forecasting process does it at the brand level
 - Brand table conforms to the atomic product table as it is a strict subset of product table

Outline

- 1 The Grocery Store Example
- 2 More about Multidimensional Modeling
- 3 Inventory Management Example
- 4 Order Management**
- 5 OncoNet
- 6 MEDAN

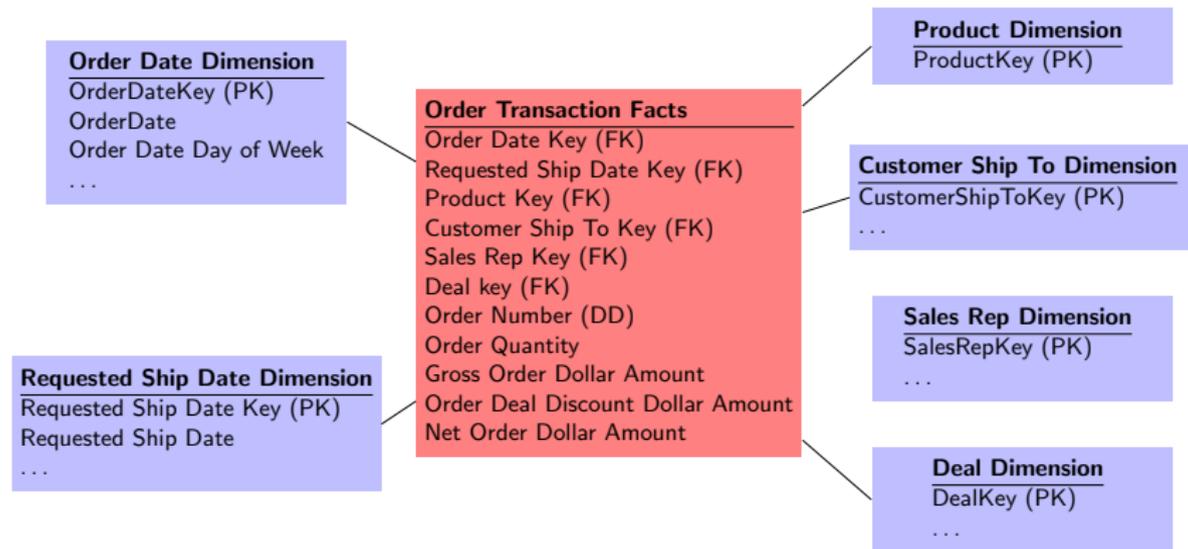

Order Management/1

- **Order management** consists of several critical **business processes** (order, shipment, invoiceprocessing, etc.) and **measures** (sales volume, invoice revenue, etc.)
- Data warehouse bus matrix

| Business Processes | Shared Dimensions | | | | | | |
|--------------------|-------------------|---------|----------|------|-----------|-----------|---------|
| | Date | Product | Customer | Deal | Sales Rep | Ship From | Shipper |
| Quotes | X | X | X | X | X | | |
| Orders | X | X | X | X | X | | |
| Shipment | X | X | X | X | X | X | X |
| Invoicing | X | X | X | X | X | X | X |

Order Management/2

• Star Schema

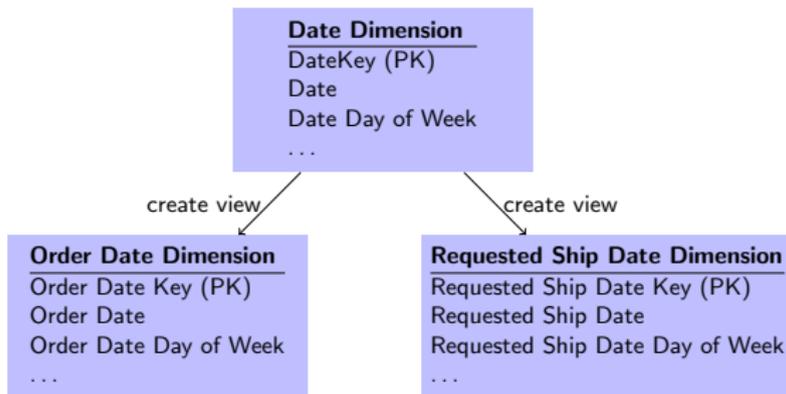

• Issues

- Should there be a “Ship Date Key” in the fact table?
- Can/should Order Date Key and Requested Ship Date Key be foreign keys to the same dimension table?

Role-Playing

- **Role-playing** in DW occurs when a **single dimension** appears **several times** in the same fact table,
 - e.g., order date and requested ship date
- Should not be FK to the same dimension table
 - SQL would require the two dates to be the same
 - We might want to constrain the two dimensions differently
- The underlying dimension may exist as a single physical table, but each of the **roles** should be presented in a **separate view with different labels**

Fact Normalization

- **Fact normalization:** Normalize the fact table and collapse all measures into a single measure along with a special **fact dimension** that identifies the type of the measure
- Makes only sense if:
 - fact table is sparsely populated and no computations are made between different measures
 - e.g., medical tests where different parameters are measured and data is sparse
- **Example:** Normalize Order Transaction Fact Table
 - Fact Dimension table has entries for Order Quantity, Gross Order Dollar Amount, Order Deal Discount Dollar Amount, Net Order Dollar Amount

Not normalized

| Order Transaction Facts |
|--|
| Order Date Key (FK) |
| Requested Ship Date (FK) |
| ... |
| Order Quantity |
| Gross Order Dollar Amount |
| Order Deal Discount Dollar Amount |
| Net Order Dollar Amount |

Normalized

| Order Transaction Facts |
|--------------------------|
| Order Date Key (FK) |
| Requested Ship Date (FK) |
| ... |
| Entry Type (FK) |
| Amount |

| Fact Dimension |
|----------------------------|
| <u>Entry Type Key (PK)</u> |
| Entry Type |
| Unit of Measurement |
| ... |

- 4 Order Management
- 5 OncoNet**
- 6 MEDAN

OncoNet/1

- Collaboration with Hospital Meran (BSc thesis of A. Heinisch)
- OncoNet is an application for the management of patients undergoing a cancer therapy
- Cancer therapy follows a treatment plan/protocol, which specifies certain events (medications, tests, etc.) at regular time points

| Event type | Event description | Date |
|-------------------|--------------------------|-----------------------|
| Data collection | Ct Thorax | Day 60, 100, 360, 720 |
| Data collection | Ct Abdomen | Day 60, 100, 360, 720 |
| Data collection | Hemogram | Day 110 |
| Medication | Zofran | Day 1 |
| Medication | Adriplastina | Day 1 |

OncoNet/2

- **Business process:** Analysis of cancer therapies
- Queries to answer:
 - How many patients with normal blood pressure after medication X?
 - Which dosages of drug A were successful to reduce parameter Y?
 - etc.
- **Granularity:** Individual events of the chemotherapy
 - Includes measurements, examinations, questionnaires, etc.

- 3 Inventory Management Example
- 4 Order Management
- 5 OncoNet
- 6 MEDAN**

MEDAN (MEdical Data Warehousing and ANalysis)

- Collaboration between the Hospital Meran and the FUB
- Objectives
 - Conduct research and create competences in the field of medical data warehousing and analysis
 - Build a BI/DW solution for the hospital
 - Administrative DW
 - Medical DW
 - Develop and apply data analysis/mining techniques

MEDAN Data Sources

- Data sources in a health care environment
 - Internal production systems (SQL, Excel, Text files, ...)
 - External information systems

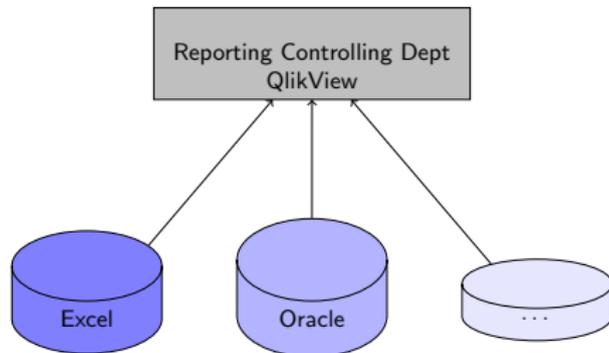

Budgeting Using a Spreadsheet

- **Example:** Budgeting in the controlling department
 - Complex and error-prone Excel spreadsheets have been used in the past
 - Monthly reports have to be sent to the Province

Budgeting Using QlickView/1

- A **QlickView** application to replace Excel
 - QlickView is a state-of-the-art data analysis tool
 - All data are kept in main memory → fast
 - Easy-to-use for small/medium sized applications
 - No solution for ETL/data staging
- Direct access to the data sources
- Data integration in QlickView
- No DW in place

Budgeting Using QlickView/2

- QlickView application: Actual budget
 - Big improvement over Excel solution

MEDAN DW Solution

- It was difficult to convince decision makers to do **proper modeling** and build a **DW as the core** of a BI solution
 - They were too much technology-driven (QlikView, ...)
- QlikView is mainly an **analysis tool** and cannot replace a DW
 - Good for quick and small ad-hoc solutions
 - Difficult to do data cleaning and hence to control data quality
 - Not scalable for many applications, changing sources, etc.
- Since Oracle technology was already in place, we finally were able to convince them to use this technology

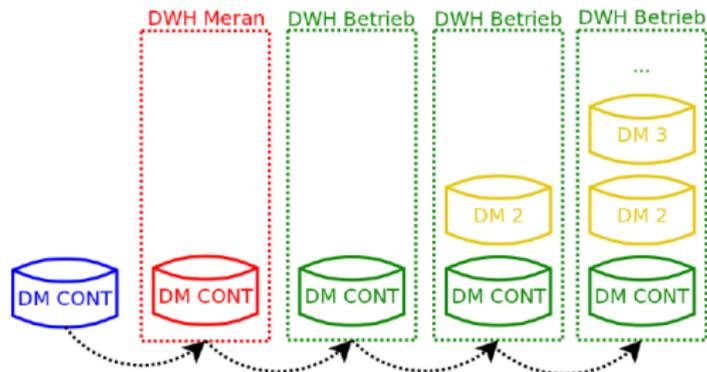

MEDAN Architecture

- Oracle ODI for ETL part and Data Storage
- Oracle DB for the DW
- QlickView and OBI for data analysis

MEDAN Bottom Up Approach

- We developed a prototype of DM CONT for the Hospital of Meran, consisting of 3 cubes:
 - Hospital Stays
 - Services
 - Transfers
- Each cube corresponds to a business process
- Goal: Deploy DM CONT in the Hospital of Meran, then in the other hospitals in South Tyrol
- Repeat the same cycle for the other DMs: DM Personnel, DM Pharmacy, DM Laboratory, etc.

Multi-valued Dimensions

- Diagnoses are an example of **multi-valued attributes/dimensions**, i.e., **many-to-many** relationships between attributes (multiple arcs in DFM)
 - a patient typically has multiple diagnoses (up to > 10)
 - books and authors is another example
- Solutions
 - Reserve **multiple columns** (one for each diagnosis)
 - Results in many empty cells, i.e., sparse fact table
 - Use **several facts** for a single hospital stay (one for each diagnosis)
 - Similar to fact normalization for measures
 - Increases the number of tuples in fact table

Multiple columns

| Hospital Stay Facts |
|-----------------------------------|
| Data Hospital Stay Admission (FK) |
| Data Hospital Stay Discharge (FK) |
| Health Record Number (FK) |
| Health Record Year (FK) |
| Patient Key (FK) |
| ... |
| Diagnosis Key 1 (FK) |
| Diagnosis Key 2 (FK) |
| Diagnosis Key 3 (FK) |
| ... |

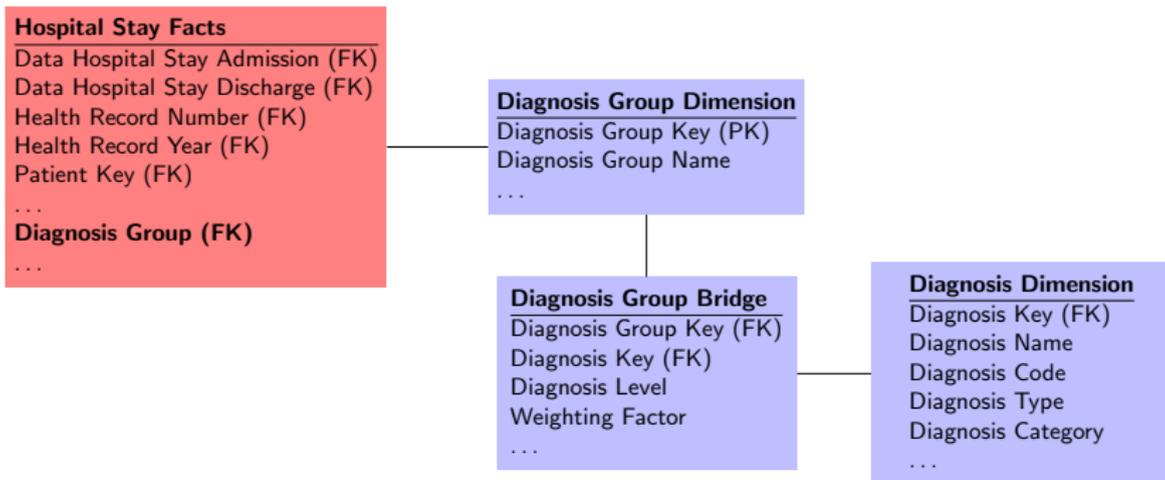

Multiple facts

| Hospital Stay Facts |
|-----------------------------------|
| Data Hospital Stay Admission (FK) |
| Data Hospital Stay Discharge (FK) |
| Health Record Number (FK) |
| Health Record Year (FK) |
| Patient Key (FK) |
| ... |
| Diagnosis Key (FK) |
| ... |

- Using **bridge tables** (next slide)

Bridge Tables

- **Bridge tables** help to deal with **multi-valued dimensions**
- Bridge table implements **two one-to-many** relationships

MEDAN Lessons Learned

- Developing a BI platform is a **process that takes years**
- A well-designed and **consistent DW is the foundation** for BI
 - QlikView is a tool for quick analyses, but cannot replace a DW
- Do not put **anything** in a single data mart
 - Use one DM for one business process (set of closely related business queries)
- Different opinions on bottom-up vs. top-down, but bottom-up seems to have more acceptance
- Data modeling is **difficult but unavoidable**
 - Helps to get a conformed view on the business
 - e.g., what is an admission/hospital stay?
 - Different granularity by different users, e.g., Province, hospital
- A **Business Intelligence Competence Center (BICC)** was missing, but would have been very helpful to
 - coordinate the whole project
 - take important decisions about the data

Summary/1

- Simplified **DW design** process by Kimball and Ross consists of 4 steps:
 - Choose business processes, granularity, dimensions, and measures
- **Surrogate key** should be used instead of operational codes
- **Degenerate dimensions** are stored in the fact table
 - or stored all together in a **junk dimension**
- DW sizing
 - **dimensions are a small portion of the DW**, hence can/should contain as much information as possible
 - **fact table determines the size** of the DW
- Dimensional model is **easy to use**, e.g., drag and drop for report generation

Summary/2

- Different Inventory models: periodic snapshot model, transactions model, accumulating
- **Shared and conformed dimensions** are crucial to integrate several DMs across a value chain
- **DW bus architecture** is a standard interface to support incremental DW design
- **DW bus matrix** is a way to document the DW bus architecture
- **Role-playing** allows to physically store a dimension only once, but use it several times in different roles and with different names
- **Fact normalization** collapses all measures into a single measure together with a special fact dimension to determine the type of the measure
 - Only useful when the fact table is sparse
- **Multi-valued dimensions** if a dimension occurs more than once in a single fact, e.g., a patient has typically several diagnoses
 - Corresponds to multiple arcs in DFM (many-to-many relationships)
- **Bridge tables** can be used to represent such dimensions
