Description Logics

Structural Description Logics: $\mathcal{FL}^-$

Enrico Franconi

franconi@cs.man.ac.uk
http://www.cs.man.ac.uk/~franconi

Department of Computer Science, University of Manchester
In the following part of this lecture, we will concentrate ourself to the simplest conceivable *structural* description logic: $\mathcal{FL}^-$. We will consider $\mathcal{FL}^-$ as a logical language: speak about:

- Syntax
- Semantics
- Reasoning problems
  - Decidability
  - Complexity
- Reasoning procedures
  - Soundness
  - Completeness
- Asymptotic complexity
The grammar

\[ C, D \rightarrow A \mid C \sqcap D \mid \forall R.C \mid \exists R \]

\( A \in \text{atomic-concept} \)

\( R \in \text{atomic-role} \)

\( C, D \in \text{concept} \)

\[
\text{concept} \ ::= \left< \text{atomic-concept} \right> \mid \\
\left< \text{concept} \right> \sqcap \left< \text{concept} \right> \mid \\
\exists \left< \text{atomic-role} \right> \mid \\
\forall \left< \text{atomic-role} \right> . \left< \text{concept} \right>
\]
Alternative grammar

\[
\text{concept} ::= \langle \text{atomic-concept} \rangle \mid \\
(\text{: and} \langle \text{concept} \rangle \ldots \langle \text{concept} \rangle) \mid \\
(\text{: some} \langle \text{atomic-role} \rangle) \mid \\
(\text{: all} \langle \text{atomic-role} \rangle \langle \text{concept} \rangle)
\]
Intuitive semantics

Intuitively (as we already know):

- **Concepts** represent classes, i.e., sets of individuals.
- **Roles** represent relations between pairs of individuals.
- Atomic concepts are the names of primitive (undefined) concepts.
- :and constructions represent conjoined concepts, so, for example, ( :and Adult Male Person) would represent the concept of something that is at the same time an adult, a male, and a person.
- This allows us to put several properties (i.e. super-concepts or attribute restrictions) together in the definition of a concept.
Quantifiers

- The :all construct provides a concept restriction on the values of an attribute \((x \text{ is an } (:\text{all } R \ C))\) if and only if each \(R\) of \(x\) is a \(C\). Thus, \((:\text{all CHILD Doctor})\) corresponds to the concept of something all of whose children are doctors. It is a way to restrict the value of a slot at a frame.

- The :some operator guarantees that there will be at least one value for the attribute named \((x \text{ is a } (:\text{some } R))\) if and only if \(x\) has at least one \(R\). For instance, \((:\text{and Person } (:\text{some CHILD}))\) would represent the concept of a parent. This is a way to introduce a slot at a frame.
Formal Semantics

An interpretation $I = (\Delta^I, \cdot^I)$ consists of:

- a nonempty set $\Delta^I$ (the *domain*)
- a function $\cdot^I$ (the *interpretation function*) that maps
  - every *concept* to a subset of $\Delta^I$
  - every *role* to a subset of $\Delta^I \times \Delta^I$
Extension of concepts

An interpretation function \( \mathcal{I} \) is an extension function iff:

\[
(C \cap D)^\mathcal{I} = C^\mathcal{I} \cap D^\mathcal{I} \\
(\forall R. C)^\mathcal{I} = \{ x \in \Delta \mid \forall y. (x, y) \in R^\mathcal{I} \Rightarrow y \in C^\mathcal{I} \} \\
(\exists R)^\mathcal{I} = \{ x \in \Delta \mid \exists y. (x, y) \in R^\mathcal{I} \}
\]

Recall that \( C^\mathcal{I} \) is a set of all the individual in the extension of \( C \): so, writing \( x \in C^\mathcal{I} \) has the same truth value as \( C(x) \). Analogously, \( (x, y) \in R^\mathcal{I} \) is the same as \( R(x, y) \).
Exercises

Choose a domain $\Delta^I$ and an extension functions over $\Delta^I$; compute the extensions of the following concepts:

- $(\text{and Adult Male})$
- $(\text{and Adult Male Rich})$
- $(\text{all CHILD} (\text{and Adult Male}))$
- $(\text{some CHILD})$
- $\exists \text{CHILD} \land \forall \text{CHILD}. (\exists \text{CHILD} \land \text{Adult})$
The subsumption problem

\[ C \sqsubseteq D \]

\( C \) is subsumed by \( D \)

iff

for any domain \( \Delta^\mathcal{I} \)

and any extension function \( \cdot^\mathcal{I} \) over \( \Delta^\mathcal{I} \):

\[ C^\mathcal{I} \subseteq D^\mathcal{I} \]

i.e.,

\[ \forall x. \ C(x) \rightarrow D(x) \]
Simple examples

• (:and Adult Male) ⊆ Adult

• (:and Adult Male Rich) ⊆ (:and Adult Male)

• (:all CHILD (:and Adult Male)) ⊆ (:all CHILD Adult)

• (:and (:all CHILD Adult) (:some CHILD)) ⊆ (:all CHILD Adult)

• (:all CHILD Adult) ⊈ (:some CHILD)

• (:some CHILD) ⊈ (:all CHILD Adult)
The universal quantifier

\[(\forall R.C)^{\mathcal{I}} = \]
Computational properties

*Subsumption* for $\mathcal{FL}^-$ has the following computational properties, which will be proved constructively:

- Decidable
- in P
The subsumption *structural* algorithm

- The algorithm for computing Subsumption is based on structural comparisons between concept expressions.
- At the heart of structural comparison is the idea that if the two concept expressions to be compared are made of subexpressions, one can compare separately one subexpression of a concept with all those of the others.
The normal form

The algorithm works in two phases: first, concepts are rewritten in a normal form, then their structures are compared.

Normal Form:

1. All nested conjunctions are flattened, i.e. \( A \sqcap (B \sqcap C) \leadsto A \sqcap B \sqcap C \).

2. All conjunctions of universal quantifications are factorized, i.e.

\[
\forall R. C \sqcap \forall R. D \leadsto \forall R. (C \sqcap D).
\]

The rewritten concepts are logically equivalent to the previous ones, hence subsumption is preserved by this transformation.

(Exercise: prove it)
The core algorithm: SUBS?[C,D]

Let $C = C_1 \sqcap \cdots \sqcap C_n$ and $D = D_1 \sqcap \cdots \sqcap D_m$ (in normal form).

Then SUBS?[C,D] returns TRUE if and only if for all $C_i$:

1. if $C_i$ is either an atomic concept, or is a concept of the form $\exists R$, then there exists a $D_j$ such that $C_i = D_j$;

2. if $C_i$ is a concept of the form $\forall R.C'$, then there exists a $D_j$ of the form $\forall R.D'$ (same atomic role $R$) such that SUBS?[C',D'].
Simple exercises

Check the following subsumption using the structural algorithm:

- (\text{:and Adult Male}) \sqsubseteq \text{Adult}
- (\text{:and Adult Male Rich}) \sqsubseteq (\text{:and Adult Male})
- (\text{:all CHILD (:and Adult Male)}) \sqsubseteq (\text{:all CHILD Adult})
- (\text{:and (:all CHILD Adult) (:some CHILD)}) \sqsubseteq (\text{:all CHILD Adult})
- (\text{:all CHILD Adult}) \not\sqsubseteq (\text{:some CHILD})
- (\text{:some CHILD}) \not\sqsubseteq (\text{:all CHILD Adult})
Asymptotic complexity

- By induction on the nesting of $\forall$-quantifiers, one can prove that the complexity of the above algorithm is $O(|C| \times |D|)$ (i.e., quadratic in the length of the longest argument).

- If subexpressions of each concept are ordered (e.g. lexicographically), then it can be shown that the complexity is only linear, so the dominant factor becomes the complexity of ordering concepts.
Soundness

Remember: whenever a sound reasoning procedure claims to have found a solution for a given instance of the problem, then this is actually a solution.

The structural subsumption algorithm is sound since, when it says that a concept $C$ subsumes a concept $D$ – i.e., $\text{SUBS?}[[C, D]$ returns true – then it holds that $D^\mathcal{I} \subseteq C^\mathcal{I}$ for all interpretations.

Observation: the part of the algorithm computing the normal form does not change the extension of the concepts for any interpretation; thus it does not affect the soundness (and the completeness) of the algorithm.
Informal proof

- Suppose that $\text{SUBS?}[C, D]$ returns $\text{TRUE}$ and consider one of the conjuncts of $C$ – call it $C_i$.
- Either $C_i$ is among the $D_j$, or it is of the form $\forall R.C'$.
- In the latter case, there is a $\forall R.D'$ among the $D_j$, where $\text{SUBS?}[C',D']$.
- Then, by induction, any extension of $D'$ must be a subset of $C''$, and so any extension of $D_j$ must be a subset of $C_i$’s.
- So, no matter what $C_i$ is, the extension of $D$ – which is the conjunction of all the $D_j$’s – must be a subset of $C_i$.
- Since this is true for every $C_i$, the extension of $D$ must also be a subset of the extension of $C$ – which is the intersection of all the extensions of $C_i$.
- So, whenever $\text{SUBS?}[C, D]$ returns $\text{TRUE}$, $C$ subsumes $D$, i.e., $D^T \subseteq C^T$. 

Completeness

Remember: whenever an instance of the problem has a solution, a complete reasoning procedure computes the solution for that instance.

The structural subsumption algorithm is complete since, whenever it holds that $C^I \subseteq D^I$ for all interpretations, then the algorithm says that $C$ subsumes $D$.

Observation: The proof is done by showing that anytime $\text{SUBS?}[C, D]$ returns FALSE, there exists an interpretation assigning an element to $D$ but not to $C$, i.e., in that interpretation the extension on $C$ is not a superset of the extension of $D$. 
Idea of the proof

- The proof is done by showing that anytime $\text{SUBS?}[C, D]$ returns FALSE, there exists an interpretation assigning an element to $D$ but not to $C$, i.e., in that interpretation the extension on $C$ is not a superset of the extension of $D$.
- This shows a counter-example, i.e., anytime $\text{SUBS?}[C, D]$ returns FALSE it is not true that $D^\mathcal{I} \subseteq C^\mathcal{I}$ for that particular interpretation, and so $C \nsubseteq D$. 
Idea of the proof (cont.)

- The proof relies on the fact that anytime SUBS?\([C, D]\) returns TRUE it is possible to find a conjunct \(C_i\) of \(C\) which has no correspondent conjunct in \(D\).

- It is shown that in this case there exists an interpretation which assigns an object to any primitive concept, but not to the factorized one \(C_i\).

- Thus, it is not possible that \(D^\mathcal{I} \subseteq C^\mathcal{I}\).
Structural algorithms (or normalize-and-compare)

What happens if we enrich the expressivity?

- CLASSIC
- BACK
- LOOM

These (old) systems have incomplete algorithms, due to the interactions between constructors, which can not be taken into account by structural algorithms, which is based on syntactical comparisons between subexpressions of the concepts.

*Example:* $A \cup \neg A$ subsumes every concept, even if such a concept does not mention at all the atomic concept $A$ in its definition.
