Abstract. Soft constraints based on semirings are a generalization of classical constraints, where tuples of variables’ values in each soft constraint are uniquely associated to elements from an algebraic structure called semiring. This framework is able to express, for example, fuzzy, classical, weighted, and over-constrained constraint problems. Classical constraint propagation has been extended and adapted to soft constraints by defining a schema for “soft local consistency” [BMR97]. On the other hand, in [Apt99c] it has been proven that most of the well known constraint propagation algorithms for classical constraints can be cast within a single schema. In this paper, we refine the framework of [Apt99c] and show how to use it for soft constraints. In doing so, we generalize the concept of soft local consistency, and we also prove some convenient properties about the termination of the proposed schema.

1 Introduction

Soft constraints allow to model faithfully many real-life problems, especially those which possess features like preferences, uncertainties, costs, levels of importance, and absence of solutions. Formally, a soft constraint problem (SCSP) is just like a classical constraint problem (CSP), except that each assignment of values to variables in the constraints is associated to an element taken from a set (usually ordered). These elements will then directly represent the desired features, since they can be interpreted as levels of preference, or costs, or levels of certainty, or many other criteria.

There are many formalizations of soft constraint problems. In this paper we consider the one based on semirings [BMR97], where the semiring specifies the partially ordered set and the appropriate operation to use to combine constraints together. This formulation has been shown to have many interesting intants, like classical, fuzzy, weighted, and probabilistic constraints.

For the semiring formalism, the propagation techniques usually used for classical CSPs have been extended and adapted to deal with soft constraints, provided
that certain conditions are met. This has led to a general framework for soft constraint propagation, where at each step a subproblem is solved, as in classical constraint propagation, and possibly some domain modifications occur in such a subproblem [BMR97]. It is important to notice that, by studying the properties of this schema, it has been proved that such steps can be seen as functions which are monotone, inflationary, and idempotent over a certain partial order.

On an orthogonal line of research, the concept of constraint propagation over classical constraints has been studied in depth in [Apt99c], and a general algorithmic schema (called GI) has been developed. In such a schema, constraint propagation is achieved whenever we have a set of functions which are monotone and inflationary over a partial order with a bottom.

By studying these two frameworks and comparing them, the first thing we noticed is that the GI schema can be applied to soft constraints (see Section 6), since the function are order used for soft constraints has all the necessary properties for the GI algorithm. This is proved in this paper by defining an appropriate partial order over soft constraint problems (see Section 4).

By analyzing the features of the GI algorithm, we also realized (see Section 5) that indeed soft constraint propagation can be extended to deal with functions which are not necessarily idempotent (but still have to be monotone and inflationary). Notice that this is a double generalization: we don’t require any longer that each step has to solve a subproblem (it could do some other operation over the problem), nor that it is idempotent. This allows us to model several forms of “approximate” constraint propagation which were instead not modelled in [BMR97]. Example are: bounds-consistency for classical constraints [MS98], and partial soft arc-consistency for soft constraints [BCGR00].

Summarizing, these two results allow us to use the GI algorithm schema for performing a generalized form of soft constraint propagation. What is important to study, at this point, is when the resulting GI schema terminates. In fact, if we work with classical constraints over finite domains, it is easy to see that the GI algorithm always terminates. However, when moving to soft constraints over a semiring, even if the variable domain is finite, we could have an infinite behaviour due to an infinite number of elements in the semiring. For example, fuzzy constraints have a semiring containing all reals between 0 and 1, while the semiring of weighted constraints contains all the reals, or all the naturals (depending on the type of weights).

Therefore in the last part of the paper (see Section 7) we focus on identifying some sufficient conditions for the termination of the GI algorithm over soft constraints. The first, predictable, condition that we consider is the well-foundedness of the partial order over soft constraint problems: if the partial order over which the GI algorithm works has chains of finite length, since constraint propagation never goes from one chain to another one, obviously the whole algorithm terminates.

The second condition is in some sense more precise, although less general. In fact, when the propagation steps are defined via the two semiring operations, then we can just consider the sub-order over semiring elements obtained by tak-
ing the elements initially appearing in the given problem, and closing it under the two operations. In fact, the GI algorithm cannot reach other elements, considering the restriction over the propagation steps. Therefore, if such a set (or a superset of it) is well-founded, the GI algorithm terminates.

These two conditions are both sufficient for termination. However, they could be difficult to check, unless the partial order has a well-known structure of which we know the well-foundedness. Nevertheless, in a special case we can formally prove that there exists a well-founded set of the shape required by the second condition above, and thus we can automatically deduce termination. This special case is related to the idempotence of the multiplicative operation of the semiring, the one that we use to combine constraints. Therefore, if this operation is idempotent, then GI terminates. For example, in classical constraints the multiplicative operation is logical and, and in fuzzy constraints it is the minimum, thus we can formally prove that algorithm GI over any classical or fuzzy constraint problem always terminates, provided that the functions are defined via the two semiring operations.

2 Soft Constraints

In the literature there have been many formalizations of the concept of soft constraint [SFV95,DFP93,FW92,FL93]. Here we refer to a specific one [BMR97] based on semirings, which however can be shown to generalize and express many of the others. In the semiring-based formalism, a soft constraint is just a constraint where each instantiation of its variables has an associated value. Combining constraints will then have to take into account such additional values, and thus the formalism has also to provide suitable operations for combination (×) and comparison (+) of tuples of values and constraints. Therefore the formalization adopted in [BMR97] uses a semiring structure, which is just a set plus two operations (that will be used for constraint combination and comparison).

Semirings and SCSPs. A semiring is a tuple ⟨A, +, ×, 0, 1⟩ such that: A is a set and 0, 1 ∈ A; + is commutative, associative and 0 is its unit element; × is associative, distributes over +, 1 is its unit element and 0 is its absorbing element.

Further, we enforce some additional properties on a semiring, leading to the notion of c-semiring (for “constraint-based”): a c-semiring is a semiring ⟨A, +, ×, 0, 1⟩ such that + is idempotent with 1 as its absorbing element and × is commutative.

A constraint system is a tuple CS = ⟨S, D, V⟩ where S is a c-semiring, D is a finite set (the domain of the variables) and V is a finite ordered set of variables.

Given a semiring S = ⟨A, +, ×, 0, 1⟩ and a constraint system CS = ⟨S, D, V⟩, a constraint is a pair (de, con) where con ⊆ V and de : D|con| → A. Therefore a constraint specifies a set con of variables and assigns each tuple of values of these variables an element of the semiring.

A Soft Constraint Satisfaction Problem (SCSP) on a constraint system CS is a pair P := ⟨C, con⟩, where con ⊆ V and C is a set of constraints: intuitively,
con represents the set of variables of interest for the constraint set C, which however may contain constraints defined on variables not in con.

Combining and projecting soft constraints. Given two constraints \( c_1 = \langle de f_1, con_1 \rangle \) and \( c_2 = \langle de f_2, con_2 \rangle \), their combination \( c_1 \otimes c_2 \) is the constraint \( \langle de f, con \rangle \) defined by \( con = con_1 \cup con_2 \) and \( de f(t) = de f_1(t \downarrow \downarrow_{con_1}) \times de f_2(t \downarrow \downarrow_{con_2}) \), where \( t \downarrow \downarrow_X \) denotes the tuple of values over the variables in \( X \), obtained by projecting tuple \( t \) from \( X \) onto \( Y \). In other words, combining two constraints means building a new constraint involving all the variables of the original one; the new constraint associates to each tuple of domain values a semiring element obtained by multiplying the elements associated by the original constraints to the appropriate subtuples.

Given a constraint \( c = \langle de f, con \rangle \) and a subset \( I \) of \( V \), the projection of \( c \) onto \( I \), written \( c \downarrow_I \), is the constraint \( \langle de f', con' \rangle \) where \( con' = con \cap I \) and \( de f'(t') = \sum_{t | t \downarrow \downarrow_{con} = t'} de f(t) \). Informally, projecting means eliminating some variables. This is done by associating each tuple \( t \) over the remaining variables a semiring element: the last one is the sum of the elements associated by the original constraint to all the extensions of the tuple \( t \) over the eliminated variables.

In brief: combination is performed via the multiplicative operation of the semiring, and projection via the additive one.

Examples. Classical CSPs are SCSPs where the chosen c-semiring is \( \text{Bool} = \langle \{ \text{false}, \text{true} \}, \lor, \land, \text{false}, \text{true} \rangle \). By means of \( \text{Bool} \) we can associate each tuple of elements in \( D \) a Boolean value, \( \text{false} \) or \( \text{true} \), then project and combine constraints via the Boolean connectives.

Fuzzy CSPs [DFP93] can instead be modeled by choosing the c-semiring \( \text{Fuzzy} = \langle [0,1], \text{max}, \text{min}, 0, 1 \rangle \). In fact, there each tuple has a value between 0 and 1: constraints are combined via the \( \text{min} \) operation and compared via the \( \text{max} \) operation. Figure 1 shows a fuzzy CSP. Variables are inside circles, constraints are represented by undirected arcs, and semiring values are written to the right of the corresponding tuples. Here we assume that the domain of the variables contains only elements \( a \) and \( b \).

![Fuzzy CSP diagram](image)

**Fig. 1.** A fuzzy CSP.

Solutions. The solution of an SCSP \( P = \langle C, con \rangle \) is the constraint \( \text{Sol}(P) = \langle \otimes C \rangle \downarrow_{con} \). That constraint is obtained by combining all constraints of \( P \) and
then projecting over the variables in con. In this way we get the constraint over con that is “induced” by the entire problem P.

For example, each solution of the fuzzy CSP of Figure 1 consists of a pair of domain values (that is a domain value for each of the two variables) and an associated semiring element. Such an element is obtained by selecting the smallest value for all the subtuples (as many as the constraints) forming the pair. For example, in the case of \( \langle a, a \rangle \) (that is, \( x = y = a \)), we compute the minimum between 0.9 (which is the value for \( x = a \)), 0.8 (which is the value for \( \langle x = a, y = a \rangle \)) and 0.9 (which is the value for \( y = a \)). Hence, the resulting value for that tuple is 0.8.

**Soft local consistency**. SCSPs can be solved by extending and adapting the typical algorithms used for classical CSPs. In particular, most of the traditional local consistency (also called propagation) algorithms can be generalized to SCSPs [BMR97].

In order to define local consistency algorithms for SCSPs, the notion of local consistency rules is introduced. The application of one of such rules consists of solving a subproblem of the given problem.

To model this, we use the notion of typed location. Informally, a typed location is just a location \( l \) (as in ordinary store-based programming languages) which has a set of variables \( \text{con} \) as type, and thus can only be assigned a constraint \( c = \langle de f, \text{con} \rangle \) with the same type. In the following we assume to have a location for every set of variables, and thus we identify a location with its type.

**Definition 1.** Given an SCSP \( P = \langle C, \text{con} \rangle \), the value \([l]_{P}\) of the location \( l \) in \( P \) is defined as the constraint \( \langle de f, l \rangle \in C \) if it exists, as \( \langle 1, l \rangle \) otherwise. Given \( n \) locations \( l_1, \ldots, l_n \), the value \([\{l_1, \ldots, l_n\}]_{P}\) of this set of locations in \( P \) is defined as the set of constraints \( \{[l_1]_{P}, \ldots, [l_n]_{P}\} \).

**Definition 2.** An assignment is a pair \( l := c \) where \( c = \langle de f, l \rangle \). Given an SCSP \( P = \langle C, \text{con} \rangle \), the result of the assignment \( l := c \) is the problem \( [l := c](P) \) defined as:

\[
[l := c](P) = \langle \{ (de f', \text{con'}) \in C \mid \text{con'} \neq l \rangle \cup c, \text{con} \rangle.
\]

Thus an assignment \( l := c \) is seen as a function from constraint problems to constraint problems, that modifies a given problem by changing just one constraint, namely the one with type \( l \). The change consists in substituting such a constraint with \( c \). If there is no constraint of type \( l \), then the constraint \( c \) is added to the given problem. In other words, the assignment \( l := c \) in \( P \) produces a new problem \( P' \) which is the same as \( P \), except that it has an additional constraint \( c \) over the variables in \( l \), and that the old constraints over \( l \) are removed. Note also that when \( |l| = 1 \) we are able to modify domains; in fact a domain can be seen as a unary constraint.

**Definition 3.** Given a semiring \( S = \langle A, +, \times, 0, 1 \rangle \) and a constraint system \( CS = \langle S, D, V \rangle \), we define the Problem Universe related to the constraint system \( CS \) as \( \mathcal{P}_{CS} = \langle V, \mathcal{C}_{CS} \rangle \).
Some notation: when no confusion can arise, we shall simply write \( P \) instead of the more cumbersome \( P_{CS} \).

**Definition 4.** Consider a constraint system \( CS = \langle S, D, V \rangle \), a location \( l \) and a set of locations \( L \), where \( l \in L \); a local consistency rule \( r^l \) is a function \( r^l : \phi(P_{CS}) \to \phi(P_{CS}) \) such that, for any \( P \in \phi(P_{CS}) \), \( r^l(P) = \text{Sol}([([L]_P, l)])(P) \).

Intuitively, the application of \( r^l \) to \( P \) adds the constraint \( \text{Sol}([([L]_P, l)]) \) over the variables in \( l \) to \( P \). This constraint, by definition of \( \text{Sol} \), is obtained by combining all constraints of \( P \) identified by \( L \) and then projecting the resulting constraint over \( l \). However local consistency rules add or modify the constraints of a problem preserving “equivalence”, which is defined as follows.

**Definition 5.** Consider two problems \( P_1 \) and \( P_2 \) such that \( \text{con}_1 \subseteq \text{con}_2 \). If they have the same solution set, we say that they are equivalent and write \( P_1 \equiv_P P_2 \).

It is possible to prove the following about the local consistency rules [BMR97]:

- (equivalence) Given a constraint system \( CS \), an SCSP \( P \) and a rule \( r \) on \( CS \), we have that \( P \equiv r(P) \) if \( r \) is idempotent.
- (inflationarity) Given an SCSP \( P \), a location \( l \) and a set of locations \( L \), we have that \( P \subseteq_C P \equiv_C r^l(P) \).
- (monotonicity) Consider two SCSPs \( P_1 = \langle C_1, \text{con}_1 \rangle \) and \( P_2 = \langle C_2, \text{con}_2 \rangle \) over \( CS \), any set of locations \( L \) and a location \( l \in L \). If \( P_1 \subseteq_C P_2 \), then \( r^l(P_1) \subseteq_C r^l(P_2) \).

**Definition 6.** Consider a problem \( P \) and a set \( R \) of rules. An infinite sequence \( T \) of rules in \( R \) is a strategy. A strategy is fair if each rule of \( R \) occurs in it infinitely often.

Since a local consistency rule is a function from problems to problems, the application of a sequence \( S \) of rules to a problem is easily provided by function composition: we write \( [r; S](P) = [S][([r_1](P))] \) and mean that the problem \( [r; S](P) \) is obtained applying first the rule \( r \) and then the rules of the sequence \( S \) in the specified order.

We are now ready to define local consistency algorithms.

**Definition 7 (local consistency algorithm).** Given a problem \( P \), a set of rules \( R \) and a fair strategy \( T \) for \( R \), a local consistency algorithm applies to \( P \) the rules in \( R \) in the order given by \( T \). The algorithm stops when the current problem is a fixpoint of all functions from \( R \). In that case, we write \( lc(P, R, T) \) to denote the resulting problem.

It is easy to prove that all the results about local consistency rules hold also for a whole local consistency algorithm. Moreover, we can prove also that the strategy does not influence the result, if it is fair [BMR97].
3 The Generic Iteration algorithm

The author of [Apt99b,Apt99c] introduced the Generic Iteration (GI) algorithm to find the least fixpoint of a finite set of functions defined on a partial ordering with bottom. This was then used as an algorithmic schema for classical constraint propagation: each step of constraint propagation was seen as the application of one of these functions. Our idea is to compare this schema with the one used for soft constraints, with the aim of obtaining a new schema which is the most general (that is, it can be applied both to classical and to soft constraints) and has the advantages of both of them.

We recall here the main definitions needed for the development of the GI algorithm.

Definition 8.

- Consider a partial ordering \( \mathcal{D} := (D, \sqsubseteq_D) \); the \( n \)-product ordering of \( \mathcal{D} \) is the ordering \( \langle D^n, \sqsubseteq_D^n \rangle \) where, for each \( n \)-tuple \( d := (d_1, \ldots, d_n) \) and \( d' := (d'_1, \ldots, d'_n) \) of \( D^n \), we have that \( d \sqsubseteq_D d' \) iff, for all \( i = 1, \ldots, n \), \( d_i \sqsubseteq_D d'_i \).
- A function \( f : \langle D^n, \sqsubseteq_D^n \rangle \rightarrow (D, \sqsubseteq_D) \) is inflationary (with respect to \( \sqsubseteq_D \)) if, for all \( d \in D^n \) and \( i = 1, \ldots, n \), \( d_i \sqsubseteq_D f(d) \).
- A function \( f : \langle D^n, \sqsubseteq_D^n \rangle \rightarrow (D, \sqsubseteq_D) \) is monotonic if \( d \sqsubseteq_D d' \) implies \( f(d) \sqsubseteq_D f(d') \).

Consider now a set of functions \( F := \{ f_1, \ldots, f_k \} \) on \( D \). The following algorithm can compute the least common fix point of the functions in \( F \).

**Generic Iteration Algorithm (GI)**

\[
\begin{align*}
d &:= \perp; \\
G &:= F; \\
\text{while } G \neq \emptyset & \text{ do} \\
& \quad \text{choose } g \in G; \\
& \quad G := G - \{ g \}; \\
& \quad G := G \cup \text{update}(G, g, d); \\
& \quad d := g(d) \\
& \text{do} \\
\end{align*}
\]

where for all \( G, g, d \) the set of functions \( \text{update}(G, g, d) \) from \( F \) is such that:

- **A.** \( \{ f \in F - G \mid f(d) = d \land f(g(d)) \neq g(d) \} \subseteq \text{update}(G, g, d) \);
- **B.** \( g(d) = d \) implies \( \text{update}(G, g, d) = \emptyset \);
- **C.** \( g(g(d)) \neq g(d) \) implies \( g \in \text{update}(G, g, d) \).

Intuitively, assumption A states that \( \text{update}(G, g, d) \) at least contains all the functions from \( F - G \) for which \( d \) is a fix point but \( g(d) \) is not. So at each loop iteration such functions are added to the set \( G \). In turn, assumption B states that no functions are added to \( G \) in case the value of \( d \) did not change. Note
that even though after the assignment $G := G - \{g\}$ we have $g \in F - G$ still $g \notin \{f \in F - G \mid f(d) = d \land f(g(d)) \neq g(d)\}$ holds. So assumption A does not provide any information when $g$ is to be added back to $G$. This information is provided in assumption C. On the whole, the idea is to keep in $G$ at least all functions $f$ for which the current value of $d$ is not a fix point.

The following theorem states the (partial) correctness of the GI algorithm, cf. [Apt99b,Apt99c].

**Theorem 1 (termination and correctness of GI).**

i. Every terminating execution of the GI algorithm computes in $d$ a common fixpoint of the functions from $F$.

ii. Suppose that all functions in $F$ are monotonic. Then every terminating execution of the GI algorithm computes in $d$ the least common fixpoint of all the functions from $F$.

iii. Suppose that all functions in $F$ are inflationary and that $D$ is finite. Then every execution of the GI algorithm terminates. □

4 Some useful orderings

In this section we review and modify some of the orderings among semiring elements, constraints, and problems, which have been introduced in [BMR97]; moreover, we also define new orderings that will be used in the next sections. These orderings will be used within the GI algorithm, which, we recall, needs to work on a partial order with a bottom.

4.1 Semiring order

Hereby, we introduce the same ordering over the semiring, and state some of the results concerning it, that can be found in [BMR97]. Then we will use this ordering to define other ordering relations.

**Definition 9.** The semiring relation $\leq_S$ over the set $A$ is defined as follows: $a \leq_S b$ iff $a + b = b$.

Intuitively, the relation $a \leq_S b$ means that $b$ is “better” than $a$, or, from another point of view, that the $+$ operation chooses $b$ between $a$ and $b$.

**Theorem 2 (($A,\leq_S$) is a po).** Given a semiring $S = \langle A,+,\times,0,1\rangle$ with $\times$ idempotent, we have the following:

- the relation $\leq_S$ is a partial order over the set $A$;
- 0 is the minimum;
- 1 is the maximum. □

The previous result corresponds to Theorem 2.3 of [BMR97]; in the same paper, the authors demonstrated stronger properties of $\leq_S$, namely that $(A,\leq_S)$ is a distributive lattice, provided that $\times$ is idempotent; as far as we are concerned, the result stated in Theorem 2 above is sufficient for our purposes.
**Proposition 1.** Let $S = \langle A, +, \times, 0, 1 \rangle$ be a semiring and $\leq_S$ the associated partial order relation. Then the following results hold:

- $+$ and $\times$ are monotone with respect to $\leq_S$;
- $+$ is inflationary with respect to $\leq_S$; instead $\times$ is inflationary with respect to $\geq_S$.

The proof of this Proposition can be found in [BMR97] within Theorem 2.4.

Summarizing, given a semiring $S$, we have two operations, $+$ and $\times$, which are both monotone over $\leq_S$. Moreover, $+$ always brings to higher elements in the partial order, while $\times$ always brings to lower elements.

### 4.2 Constraint order

From the ordering $\leq_S$ over $A$, we can also define a corresponding order between constraints. Before introducing the new order we define its domain, namely the set of all possible constraints over a constraint system.

**Definition 10.** Given a semiring $S = \langle A, +, \times, 0, 1 \rangle$ and a constraint system $CS = \langle S, D, V \rangle$, we define the Constraint Universe related to the constraint system $CS$ as follows: $C_{CS} = \bigcup_{\text{con} \in V} \{ \langle de_f, \text{con} \rangle \mid \text{de}_f : D^{\text{con}} \rightarrow A \}$.

Some notation: we write $\mathcal{C}$ (instead of $C_{CS}$) when the constraint system $CS$ is clear from the context.

**Definition 11.** Consider two constraints $c_1, c_2$ over a constraint system $CS$; assume that $\text{con}_1 \subseteq \text{con}_2$ and $|\text{con}_2| = k$. Then we write $c_1 \sqsubseteq_S c_2$ if and only if, for all $k$-tuples $t$ of values from $D$, $\text{de}_f(t) \leq_S \text{de}_f(t^\text{con}_2)$.

Loosely speaking, a constraint $c_1$ is less than $c_2$ in the order $\sqsubseteq_S$ iff it constrains possibly less variables and assigns each tuple a greater value with respect to $\leq_S$ than $c_2$ does.

**Remark 1.** Notice that the above definition is slightly different from the one stated in [BMR95,BMR97], since there only constraints over the same set of variables were taken into account. In this case, our order is the reverse of the one considered in [BMR97].

**Theorem 3 (\(\sqsubseteq_S\) is a po).** Given a semiring $S = \langle A, +, \times, 0, 1 \rangle$ with $\times$ idempotent and a constraint system $CS = \langle S, D, V \rangle$ we have the following:

- the relation $\sqsubseteq_S$ is a partial order over the set $C_{CS}$;
- its bottom $\perp_S$ is $\langle 1, \emptyset \rangle$, where the 0-arity function $1 : \emptyset \rightarrow A$ is the constant $1$ of the semiring.

**Proof.** We prove our first claim: we need to demonstrate that $\sqsubseteq_S$ is a reflexive, antisymmetric and transitive relation. Reflexivity holds trivially. To prove antisymmetry, suppose that $c_1 \sqsubseteq_S c_2$ and $c_2 \sqsubseteq_S c_1$; this yields that $\text{con}_1 = \text{con}_2$. Now, for all $t \in D^{\text{con}_1}$, we have both $\text{de}_f(t) \leq_S \text{de}_f(t)$ and $\text{de}_f(t) \leq_S \text{de}_f(t)$, hence $\text{de}_f(t) = \text{de}_f(t)$ and so $c_1 = c_2$. The transitivity of $\sqsubseteq_S$ follows from the transitivity of $\leq_S$. The other claim immediately follows from the definition of $\sqsubseteq_S$. 

□
4.3 Constraint set order

We can easily extend the order $\sqsubseteq_S$ over constraints to a new order over constraint sets as follows.

**Definition 12.** Consider two sets of constraints $C_1, C_2$ over a constraint system $CS$. Suppose furthermore that $C_1 = \{c_i^1 : i \in I\}$, $C_2 = \{c_j^2 : j \in J\}$, $I \subseteq J$ and that, for every $i \in I$, the relation $c_i^1 \subseteq_S c_i^2$ holds. Then we write $C_1 \sqsubseteq_C C_2$.

The intuitive reading of $C_1 \sqsubseteq_C C_2$ is that $C_2$ is a problem generally “more constraining” than $C_1$ is, because $C_2$ has (possibly) a larger number of “more restrictive” constraints than $C_1$ has.

**Note 1.** Observe that the relation $\subseteq$ is a $\sqsubseteq_C$ relation. Indeed, consider two sets of constraints $C_1, C_2$ over a constraint system $CS$: if $C_1 \subseteq C_2$ then $C_1 \sqsubseteq_C C_2$. In particular, for every constraint set $C$ over $CS$, we have that $C \sqsubseteq_C C$.

**Theorem 4 ($\sqsubseteq_C$ is a partial order).** Given a semiring $S = \langle A, +, \times, 0, 1 \rangle$, and a constraint system $CS = \langle S, D, V \rangle$, the following statements hold:

- the relation $\sqsubseteq_C$ is a partial order over $\wp(C)$;
- the bottom of the relation is $\perp_{\wp(C)}$ is $\emptyset$.

**Proof.** We only prove the first claim, the other one being straightforward. As usual, we need to prove that the relation $\sqsubseteq_C$ is reflexive, antisymmetric and transitive. Reflexivity trivially holds. As far as antisymmetry is concerned, suppose that $C_1 = \{c_i^1 : i \in I\}$, $C_2 = \{c_j^2 : j \in J\}$ and both $C_1 \sqsubseteq C_2$ and $C_2 \sqsubseteq C_1$ hold; this means that $I = J$. Moreover, the following relations hold for every $i \in I$: $c_i^1 \subseteq_S c_i^2$ and $c_i^2 \subseteq_S c_i^1$. Hence $c_i^1 = c_i^2$ for every $i \in I$, because $\subseteq_S$ is a partial order relation, cf. Theorem 3. Transitivity follows similarly exploiting the transitivity of $\subseteq_S$. \qed

4.4 Problem order

So far, we have introduced two partial ordering relations: one between constraints ($\subseteq_S$) and another one between constraint sets ($\subseteq_C$). However, local consistency algorithms take constraint problems as input; therefore we need an ordering relation between problems if we want the GI algorithm to be used for soft local consistency.

**Definition 13.** Given a constraint system $CS$, consider two problems $P_1 = \langle C_1, con_1 \rangle$ and $P_2 = \langle C_2, con_2 \rangle$ on it. We write $P_1 \sqsubseteq_{CP} P_2$ iff $C_1 \sqsubseteq_C C_2$ and $con_1 \subseteq con_2$.

**Note 2.** As observed in Note 1, the partial order $\subseteq$ between constraint sets is a $\subseteq_C$ relation; analogously, the set inclusion $\subseteq$ between SCSP’s is a $\subseteq_{CP}$ relation. Given a constraint system $CS = \langle S, D, V \rangle$ and a problem $P = \langle C, con \rangle$, we have that $P \subseteq P'$ implies $P \sqsubseteq_{CP} P'$. 
We now need to define a partially ordered structure that contains all SCSPs that can be generated via local consistency starting from a given problem. We recall that a local consistency algorithm for SCSPs modifies a given problem enforcing new constraints on it.

**Definition 14.** Consider a constraint system CS and an SCSP P over it. The up-closure of P, briefly P ↑, is the class of all problems P' on CS such that P ⊆ CS P'.

The proof of the following proposition is an immediate consequence of the previous definition and the fact that ⊆ C is a transitive relation, cf. Theorem 4.

**Proposition 2.** Consider a constraint system CS, an SCSP P over it and its up-closure P ↑. Then the following statements hold:

1. if P_1 ⊆ CS P_2 and P_1 ∈ P ↑, then P_2 ∈ P ↑;
2. if P_1 ⊆ CS P_2, then P_2 ↑ ⊆ P_1 ↑.

**Theorem 5 (⊆CP is a po).** Given a constraint system CS = (S,D,V) and a problem P on it, the following statements hold:

- the relation ⊆ CP is a partial order between problems on CS;
- in particular ⟨P ↑, ⊆ CP|P↑⟩ is a partial ordering, where ⊆ CP|P↑ is the restriction of ⊆ CP to P ↑; when no confusion can arise, we simply write ⟨P ↑, ⊆ CP⟩;
- the bottom ⊥ CS of ⟨P ↑, ⊆ CP⟩ is P.

**Proof.** We prove the first claim, the other ones following immediately from the definition of P ↑ and Proposition 2. As usual, we only prove that the relation is antisymmetric, because transitivity can be proved similarly and reflexivity trivially holds. Hence, suppose that both P_1 ⊆ CP P_2 and P_2 ⊆ CP P_1 hold. This means that we have the following relations:

\[ con_1 ⊆ con_2 \text{ and } C_1 ⊆ C_2, \]
\[ con_2 ⊆ con_1 \text{ and } C_2 ⊆ C_1. \]

From the two previous relations and Theorem 4, it follows that con_1 = con_2 and C_1 = C_2; hence P_1 = P_2. \(\square\)

5 **Generalized local consistency for soft constraints**

The local consistency rules defined in [BMR97], and recalled in Section 2, solve a subproblem of a given problem. Such rules are shown to be monotone, inflationary, and idempotent. However, algorithm GI just needs a set of functions which are monotone and inflationary. We recall that inflationarity is needed to ensure correctness (that is, that the least fixpoint is generated), while monotonicity ensures, together with the finiteness of the domain, that GI terminates. Therefore, we will now define a generalized notion of local consistency rules for soft constraints, which have just these two properties.
Definition 15. Consider an SCSP problem $P$ over a semiring $S$. A local consistency function for $P$ is a function $f : P \uparrow \rightarrow P \uparrow$ which is monotone and inflationary over $\sqsubseteq_{CP}$.

With this definition of a local consistency function we relax two conditions about a local consistency step:

- that it must solve a subproblem;
- that it must be idempotent.

The second generalization has been triggered by the results about the GI algorithm, which have shown that idempotency is not needed for the desired results. Moreover, many practical local consistency algorithms do not exactly solve subproblems, but generate an approximation of the solution (see for example the definition of bounds consistency in [MS98]). Thus the first extension allows one to model many more practical propagation algorithms.

6 Soft constraint propagation via algorithm GI

We can now collect the results achieved so far and combine them together in this section. Our goal is to exploit the GI algorithm introduced in Section 3 and apply it to local consistency functions for soft constraints.

The functions that GI needs in input are defined on a partial order with bottom. In the case of local consistency rules for SCSPs, the partial order is $\langle P \uparrow, \sqsubseteq_{CP} \rangle$, and the bottom is the problem $P$ itself, cf. Theorem 5. Moreover, the local consistency rules (and also the more general local consistency functions) have all the “good” properties that GI needs. Namely, those functions are monotonic and inflationary. Thus algorithm GI can be used to perform constraint propagation over soft constraint problems. Notice that the possibility of using local consistency functions, instead of the more restrictive local consistency rules, allows also to model partial local consistency (such as bounds-consistency or partial arc-consistency [BCGR00]).

This result can be formally stated as follows, as a corollary of Theorem 1.

Corollary 1 (properties of GI over soft constraints). Given a constraint system $CS$ and an SCSP problem $P$ on it, let us instantiate the GI algorithm with the po $\langle P \uparrow, \sqsubseteq_{CP} \rangle$ and a finite set $R$ of local consistency functions. Then every terminating execution of the GI algorithm computes in the output problem $P'$ the least common fixedpoint of all the functions from $R$.

This means that algorithm GI can be applied as it is to soft constraint problem. In fact, if given in input a set of local consistency functions for a given SCSP problem $P$, the algorithm performs constraint propagation over $P$.

What is now important to investigate is when the algorithm terminates. This is particularly crucial for soft constraints, since, even when the variable domains are finite, the semiring may contain an infinite number of elements, which is obviously a source of possible infiniteness. In the next section we will provide some useful sufficient conditions for the termination of the GI algorithm when used for constraint propagation over soft constraints.
7 Termination of the GI algorithm over soft constraints

As noted above, the presence of a possibly infinite semiring may lead to a constraint propagation algorithm which does not terminate. In the following we will give several independent conditions which guarantee termination in some special cases.

The first condition is a predictable extension of the one given in Theorem 1: instead of requiring the finiteness of the domain of computation, we just require that its chains have finite length, since it is easy to see that constraint propagation moves along a chain in the partial order. Monotonicity and inflationarity are assured since they are properties, by definition, of the local consistency functions (which, we recall, extend the local consistency rules defined in [BMR97]).

**Theorem 6 (termination 1).** Given a constraint system CS and an SCSP problem P on it, let us instantiate the GI algorithm with the po \( \langle P, \uparrow, \subseteq_{CS} P \rangle \) and a finite set R of local consistency functions. Suppose that the order \( \subseteq_{CS} \) restricted to \( P \uparrow \) is well-founded; namely that each chain of problems of \( P \uparrow \)

\[
\cdots \subseteq_{CS} P_i \subseteq_{CS} \cdots \subseteq_{CS} P_1 \subseteq_{CS} P_0
\]

is finite. Then every execution of the GI algorithm terminates.

This theorem can be used to prove termination in many cases. For example, classical constraints over finite domains generate a partial order which is finite (an thus trivially well-founded), so the above theorem guarantees termination. Another example occurs when dealing with weighted soft constraints, where we deal with the naturals. Here the semiring is \( \langle N, +, min, 0, +\infty \rangle \). Thus we have an infinite order, but well-founded.

However, there are also many interesting cases in which the ordering \( \langle P, \uparrow, \subseteq_{CS} P \rangle \) is not well-founded. Consider for instance the case of fuzzy or probabilistic CSPs. For fuzzy CSPs, the semiring is \( \langle [0,1], min, max, 0, 1 \rangle \). Thus the partially ordered structure containing all problems smaller than the given one, according to the semiring partial order, is not well-founded, since we have all the reals between 0 and a certain element in [0,1]. Thus the above theorem cannot say anything about termination of GI in this case. However, this does not mean that GI does not terminate, but only that the theorem above cannot be applied. In fact, later we will give another sufficient condition which will guarantee termination in these two cases as well.

In fact, if we restrict our attention to local consistency functions defined via + and \( \times \), we can define another condition on our input problem that guarantees the termination of the GI algorithm; this condition exploits the fact that the local consistency functions are defined by means of the two semiring operations, and the properties of such operations.

**Definition 16 (semiring closure).** Consider a constraint system CS with semiring \( S = \langle A, +, \times, 0, 1 \rangle \), and an SCSP P on CS. Consider also the set of semiring values appearing in P: \( Cl(P) = \bigcup_{(def', \text{conf'}) \in CS} def'(D^{\text{conf}}') \). Then, a semiring closure of P is any set B such that:
- \( \text{Cl}(P) \subseteq B \subseteq A; \)
- \( B \) is closed with respect to + and \( \times; \)
- \( B \) is well-founded.

**Theorem 7 (termination 2).** Consider a constraint system \( CS \) with semiring \( S = \langle A, +, \times, 0, 1 \rangle \), an SCSP \( P \) on it and a finite set of local consistency functions \( R \) defined via + and \( \times \). Assume also there exists a semiring closure of \( P \). Then every execution of the GI algorithm terminates.

**Proof.** The proof is similar to the one of Theorem 1; just replace the order \( \succeq_{CP} \) with \( <_S \) and accordingly the set \( D \) with \( B \), where \( B \) is a semiring closure of \( P \). \( \square \)

**Remark 2.** Notice that this theorem is similar to the one in [BMR97] about termination; however the authors of [BMR97] force the set \( B \) to be finite in order to guarantee the termination of a local consistency algorithm (cf. Theorem 4.14 of [BMR97]); a hypothesis that is implied by ours.

For example, if we have a fuzzy constraint problem, then we can take \( B \) as the set of all semiring values appearing in the initial problem. In fact, this set is closed with respect to min and max, which are the two semiring operations in this case. Moreover, it is well-founded, since it is finite.

Another example is constraint optimization over the reals: if the initial problem contains only natural numbers, then the set \( B \) can be the set of all naturals, which is a well-founded subset of the reals and it is closed w.r.t. + (min) and \( \times \) (sum).

Therefore, by using Theorem 7 we can prove that also constraint propagation over fuzzy constraint problems always terminates, provided that each step of the algorithm uses a local consistency function which is defined in terms of the two semiring operations only.

However, it is not always easy to find a semiring closure of a given SCSP \( P \), mainly because we should check that a tentative set \( B \), closed and containing \( \text{Cl}(P) \), is well-founded. Nevertheless, there is a special case in which we don’t have to find such a set, because we can prove that it exists (and this is what Theorem 7 requires).

This special case occurs when the multiplicative operation of the semiring is idempotent. In fact, we can prove that in this case there exists always a finite (and thus well-founded) semiring closure of any given problem over that semiring. This obviously is very convenient, since it provides us with an easy way to check whether Theorem 7 can be applied.

**Theorem 8 (idempotence of \( \times \) and termination).** Consider a constraint system \( CS \), an SCSP \( P \) on it and a finite set of local consistency functions \( R \) defined via + and \( \times \). Assume also that \( \times \) is idempotent. Then there exists a finite set \( B \) which is a semiring closure of \( P \).

**Proof.** .................
Consider again the fuzzy constraint example. Here $\times$ is min, thus it is idempotent. Therefore, by Theorem 8 and 7, GI over such problems always terminates. This is an alternative, and easier, way (to Theorem 7) to guarantee that soft constraint propagation over fuzzy constraints terminates. In fact, we don’t have to find a semiring closure of the problem, but just check that the multiplicative operation is idempotent.

Considering all the above results, we can devise the following steps towards proving the termination of algorithm GI on a soft constraint problem $P$ over a semiring $S$:

- If the local consistency functions are defined via the two operations of $S$, and the multiplicative operation of $S$ is idempotent, then GI terminates (by Theorem 8).
- If instead it is not idempotent, but we still have local consistency functions defined via the two semiring operations, we can try to find a semiring closure of $P$. If we find it, then GI terminates (by Theorem 7).
- If we cannot find a semiring closure of $P$, or the local consistency functions are more general, then we can try to prove that the partial order of problems is well-founded. If it is so, the GI terminates (by Theorem 6).

While Theorem 8 applies in a special case of the hypothesis of Theorem 7, it is interesting to investigate the relationship between the hypothesis of Theorem 6 and 7. What can be proved is that these two conditions, namely, the well-foundedness of the partial order of problems and the existence of a semiring closure, are independent. In other words, there are cases in which one holds and not the other one, and vice versa. To prove this result, we need the following formal development.

**Definition 17.** Let $S = \langle A, +, \times, 0, 1 \rangle$ be a semiring and $B$ a subset of $A$. The set $B$ is a down-set (or an order ideal) if, whenever $a \in B$, $a' \in A$ and $a' \leq_S a$, then $a' \in B$. Given any subset $B$ of $A$, the downward closure of $B$ is

$$B \downarrow := \{ d' \in A : \exists d (d \in B \text{ and } d' \leq_S d) \}.$$  

Observe that the class $\mathcal{F}$ of down-sets containing a subset $B$ of $A$ is not empty, since $A$ itself is such a set. Moreover, it is easy to check that the downward closure of $B$ is the smallest down-set of $\mathcal{F}$; hence the downward closure of a set is well defined.

Given a semiring $S = \langle A, +, \times, 0, 1 \rangle$, the following result links the upward closure of a problem $P$ with the downward closure of $Cl(P)$, thus allowing us to link the conditions in the two theorems 6 and 7.

**Proposition 3.** Given a constraint system $CS$ and a problem $P$ defined on it, consider the set

$$B := \{ \langle df(t) \rangle \in A : \exists P' \in P \uparrow (c := \langle df \cdot con \rangle) \in P', \ t \in D^{\vert con \vert} \}.$$  

Then $B = Cl(P) \downarrow$. 
Proof. It follows immediately from the definition of $\subseteq_{CP}$, of $P \uparrow$ and $Cl(P) \downarrow$.

Now we can notice that, if a subset $B$ of a semiring is finite and closed with respect to $+$ and $\times$, then so is the set $\hat{B} := B \cup \{0, 1\}$. In fact it is sufficient to check that the following identities hold because of the fact that $S = \langle A, +, \times, 0, 1 \rangle$ is a $c$-semiring:

- if $a \in B$ then $a + 0 = a \in B$;
- if $a \in B$ then $a \times 1 = a \in B$;
- if $a \in B$ then $a + 1 = 1 \in \hat{B}$;
- if $a \in B$ then $a \times 0 = 0 \in \hat{B}$.

Hence in Theorem 7 we can replace the hypothesis “$Cl(P) \subseteq B$, and $B$ finite and closed with respect to $+$ and $\times$” with the condition that “$Cl(P)$ is a subset of a finite sub-$c$-semiring $B$ of $S = \langle A, +, \times, 0, 1 \rangle$”.

Moreover, $+$ is the least upper bound operation and, if $\times$ is idempotent, $\times$ is the greatest lower bound operation, cf. Theorem 2.9 and 2.10 of [BMR97]. Hence a sub-$c$-semiring is also a sub-lattice of $S = \langle A, +, \times, 0, 1 \rangle$ and vice versa if $\times$ is idempotent. Thus a subset $B$ of a semiring can be a down-set and yet it may be not closed with respect to $\times$ and $\ast$. For instance, the set of negative real numbers augmented with $-\infty$ is a down-set in the lattice $R^\infty$ of reals extended with $\{+\infty, -\infty\}$ and the usual linear ordering; however it is not a sub-lattice itself. Vice versa, there are sub-lattices of $R^\infty$ - hence sets that are closed with respect to the least upper bound and the greatest lower bound operations - that are not down-sets. For instance, the extended interval $[0, 1] \cup \{+\infty, -\infty\}$. Therefore the two conditions that guarantee the termination of algorithm $GI$ in Theorems 6 and 7 are independent.

8 Conclusions

We have studied the relationship between the soft constraint formalism based on semirings described in [BMR97] and the constraint propagation schema proposed in [Apt99]. What we have discovered is that the GI algorithm of [Apt99] can be used also for soft constraints, since soft constraints provide what is needed for the GI algorithm to work correctly: a partial order with a bottom, and a set of monotone functions.

Moreover, in studying this relationship we have also discovered that, in soft constraints, we don’t have to restrict ourselves to local consistency functions which solve a subproblem, but we can use any monotone function. Of course, in this more general case, the equivalence of the resulting problem and the initial one is not assured any more, and has to be studied on a case-by-case basis.

By passing from classical constraints to soft constraints, although on finite domains, we have more possible sources of non-termination for the GI algorithm, since the semiring can be infinite. Therefore we have studied in depth the issue of termination for GI over soft constraints, finding some convenient sufficient conditions. In particular, one of them just requires to check, in a certain special case, that the multiplicative operation of the semiring is idempotent.
