Introduction to Database Systems

Motivation

Werner Nutt

1

Databases Are Everywhere

- Database = a large (?) collection of related data
- Classically, a DB models a real-world organisation (e.g., enterprise, university)
 - Entities (e.g., students, courses)
 - Relationships (e.g., "Martin is taking IDS in 2010/11")
- Changes in the organisation = changes in the database
- Examples:
 - personnel records
 - banking
 - airline reservations

Scientific Databases (Examples)

- Biology:
 - e.g., DNA sequences of genes, amino-acid sequences of proteins, genes expressed in tissues

(up to several Gigabytes)

- Astronomy:
 - e.g., location and spectra of astronomic objects (up to several Terabytes)
- Physics:
 - e.g., sensor measurements in particle physics experiments

(up to several Petabytes)

3

DB Tendencies

- Sensors record data
 - → DBs grow in size
 - → DBs become more widespread
 - → date may be less reliable, i.e., uncertain
- Multimedia data
 - → Requirements for larger storage
 - → New query operations

(e.g., find a song by humming the melody, find pictures with a given face)

- Data on the Web
 - → Accessed/changed by many people (Facebook,...)
 - → Speed up access, loosen consistency (NoSQL)

Operations with Databases

Design

- Define structure and types of data

Construction

Create data structures of DB, populate DB with data

Manipulation of Data

- Insert, delete, update
- Query: "Which department pays the highest salary?"
- Create reports:

"List monthly salaries of employees, organised by department, with average salary and total sum of salaries for each dept"

5

An Ideal DB Implementation Should Support:

- Structure
 - data types
 - data behaviour
- Persistence
 - store data on secondary storage
- Retrieval
 - a declarative query language
 - a procedural database programming language

- Performance
 - retrieve and store data quickly
- Data Integrity
- Sharing
 - concurrency
- Reliability and resilience
- Large data volumes

Database Management System (DBMS)

- A DBMS is a software package designed to store and manage databases
- A DBMS provides generic functionality (see previous slide) that otherwise would have to be implemented over and over again
 - → Reduced application development time
- Several brands, e.g.,
 - Oracle Xi/Yg (Oracle), DB2 (IBM), SQL Server, Access (Microsoft), MySQL, PostgreSQL, HSQLDB, SQLite (open source)

7

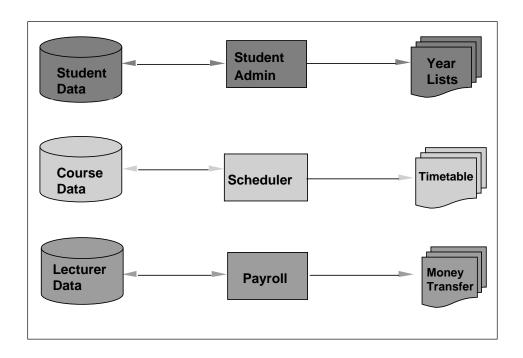

Database Actors

Application Database Designers Programmers Database End Users sophisticated Administrator casual (DBA) · 'parametric' or 'canned' transactions **Database** DBMS developers Operators and Maintenance Personnel Tool Developers **Database Management System**

"on the scenes"

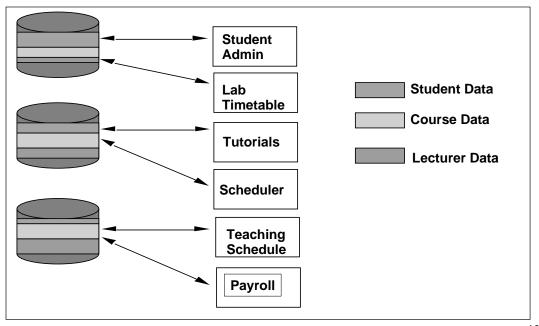

"behind the scenes"

File System: A Physical Interface

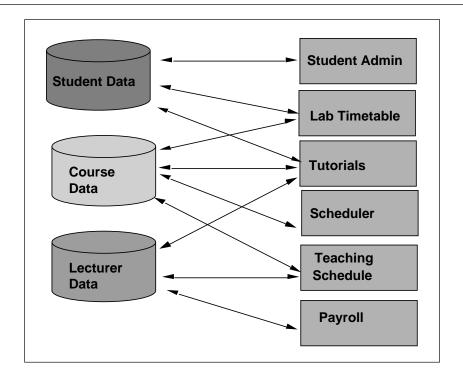

9

Sharing Data: Replication → Redundancy

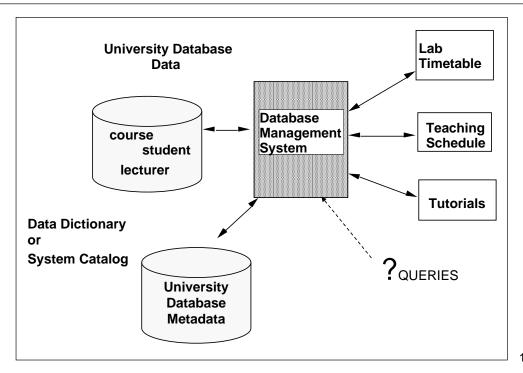

Sharing Data and Operations

11

DBMS: A Logical Interface

File System Approach

- Uncontrolled redundancy
- Inconsistent data
- Inflexibility
- Limited data sharing
- Poor enforcement of standards
- Low programmer productivity
- Excessive program maintenance
- Excessive data maintenance

13

DBMS Approach

- Controlled redundancy
 - consistency of data & integrity constraints
- Integration of data
 - self-contained
 - represents semantics of application
- Data and operation sharing
 - multiple interfaces

- Services & controls
 - security & privacy controls
 - backup & recovery
 - enforcement of standards
- Flexibility
 - data independence
 - data accessibility
 - reduced program maintenance
- Ease of application development

However....

If an application is

- simple
- stringent real-time
- single user
- static,

files are the option of choice

DBMS downside:

- more expensive
- more complex
- general

Summary:

- In a file system, data is physically accessed and not integrated
- In a DBMS, data is logically accessed and integrated:
 - query language
 - data dictionary
