

Introduction to Database Systems

Motivation

Werner Nutt

Databases Are Everywhere

- **Database** = a large (?) collection of related data
- Classically, a DB **models** a real-world organisation (e.g., enterprise, university)
 - **Entities** (e.g., students, courses)
 - **Relationships** (e.g., “Martin is taking IDS in 2010/11”)
- Changes in the organisation = changes in the database
- Examples:
 - personnel records
 - banking
 - airline reservations

Scientific Databases (Examples)

- **Biology:**
e.g., DNA **sequences** of genes, amino-acid sequences of proteins, **genes** expressed in tissues
(up to several Gigabytes)
- **Astronomy:**
e.g., **location** and **spectra** of astronomic objects
(up to several Terabytes)
- **Physics:**
e.g., **sensor measurements** in particle physics experiments
(up to several Petabytes)

DB Tendencies

- **Sensors** record data
 - ➔ DBs grow in size
 - ➔ DBs become more widespread
 - ➔ data may be less reliable, i.e., uncertain
- **Multimedia** data
 - ➔ Requirements for larger storage
 - ➔ New query operations
(e.g., find a song by humming the melody,
find pictures with a given face)
- Data on the **Web**
 - ➔ Accessed/changed by many people (Facebook,...)
 - ➔ Speed up access, loosen consistency (NoSQL)

Operations with Databases

- **Design**
 - *Define* structure and types of data
- **Construction**
 - *Create* data structures of DB, *populate* DB with data
- **Manipulation of Data**
 - *Insert, delete, update*
 - *Query*: “Which department pays the highest salary?”
 - Create *reports*:
 - “List monthly salaries of employees, organised by department, with average salary and total sum of salaries for each dept”

An Ideal DB Implementation Should Support:

- Structure
 - data types
 - data behaviour
- Persistence
 - store data on secondary storage
- Retrieval
 - a declarative query language
 - a procedural database programming language
- Performance
 - retrieve and store data quickly
- Data Integrity
- Sharing
 - concurrency
- Reliability and resilience
- Large data volumes

Database Management System (DBMS)

- A DBMS is a software package designed to *store* and *manage* databases
- A DBMS provides *generic functionality* (see previous slide) that otherwise would have to be implemented over and over again
 - ➔ *Reduced application development time*
- Several brands, e.g.,
 - Oracle Xi/Yg (Oracle), DB2 (IBM), SQL Server, Access (Microsoft), MySQL, PostgreSQL, HSQLDB, SQLite (open source)

Database Actors

**Database
Designers**

**Application
Programmers**

**Database
Administrator
(DBA)**

End Users

- sophisticated
- casual
- 'parametric' or
'canned' transactions

Tool Developers

Database Management System

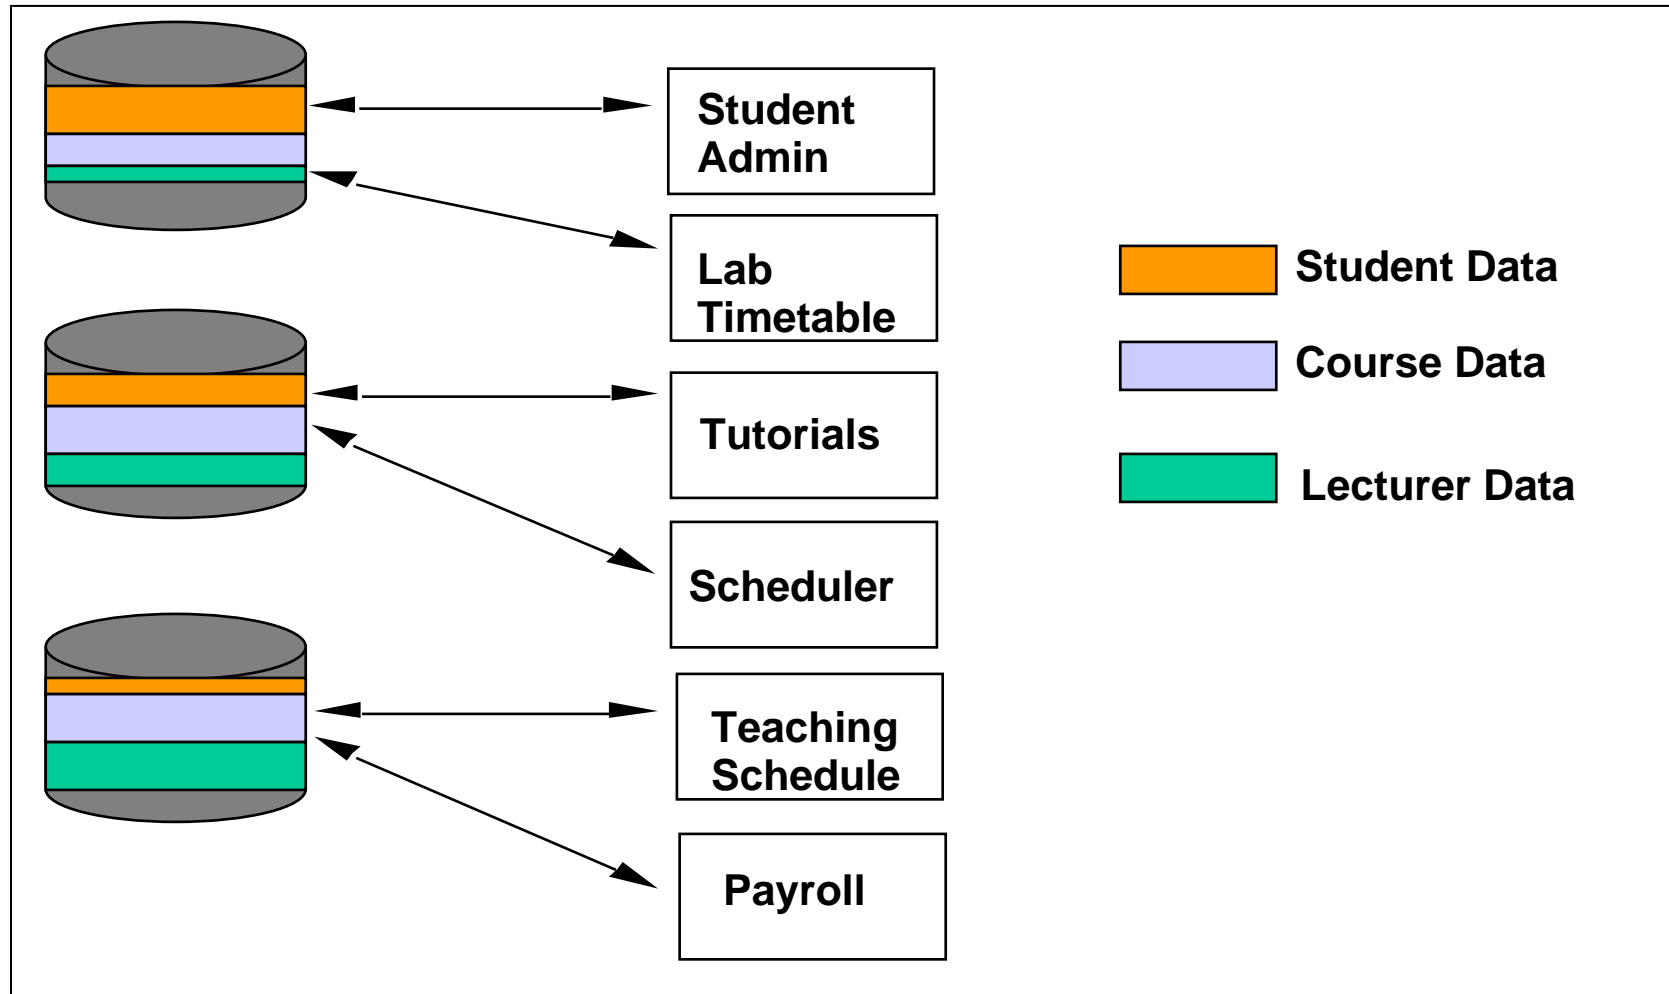

"on the scenes"

"behind the scenes"

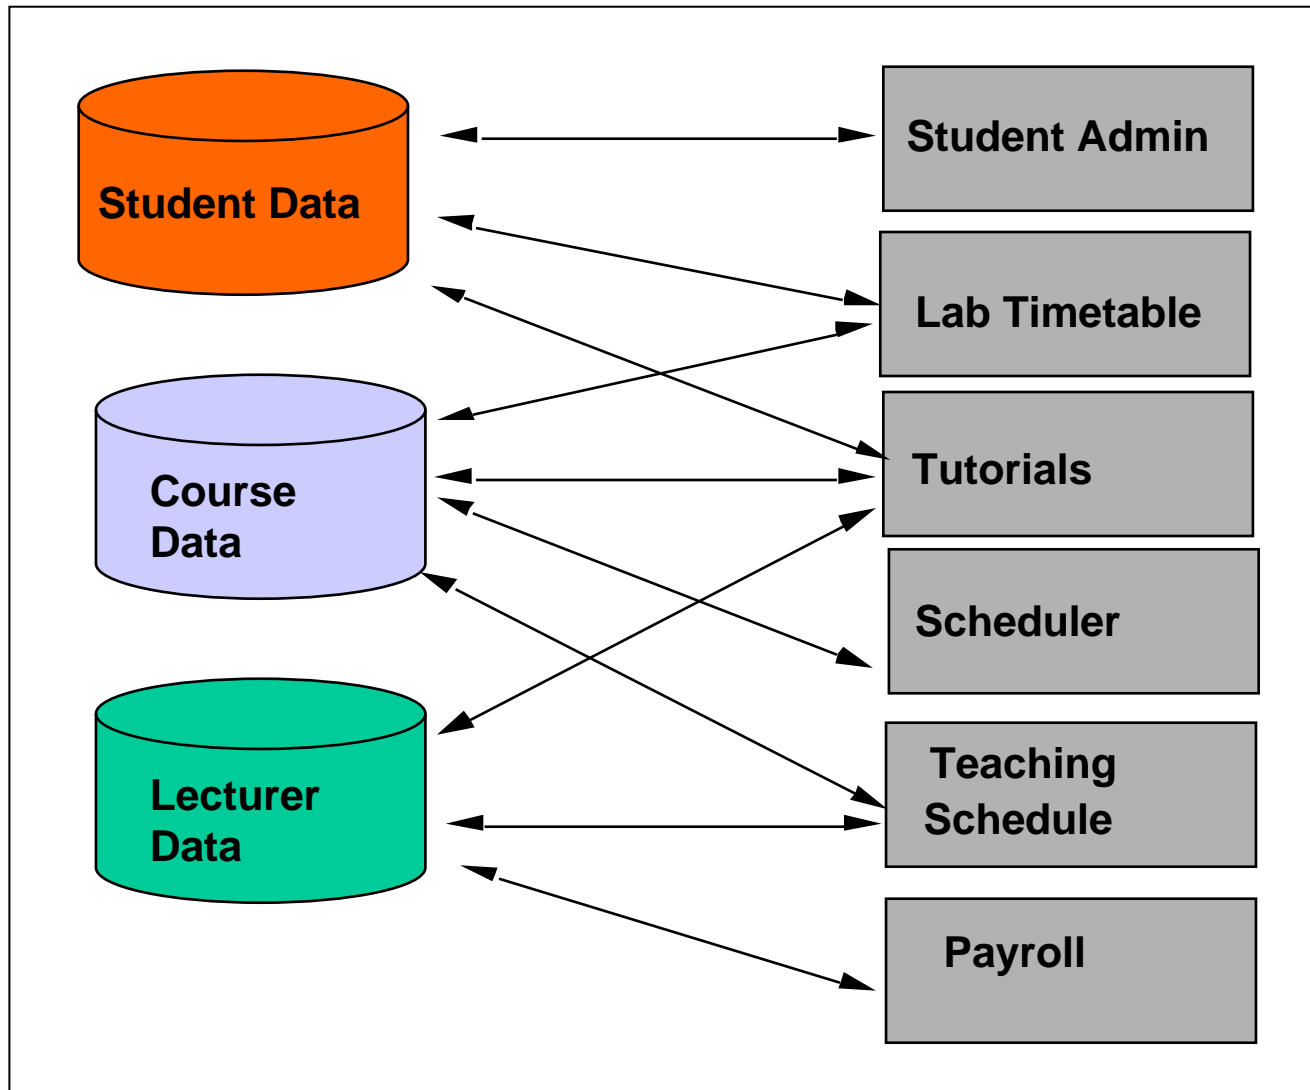

File System: A Physical Interface

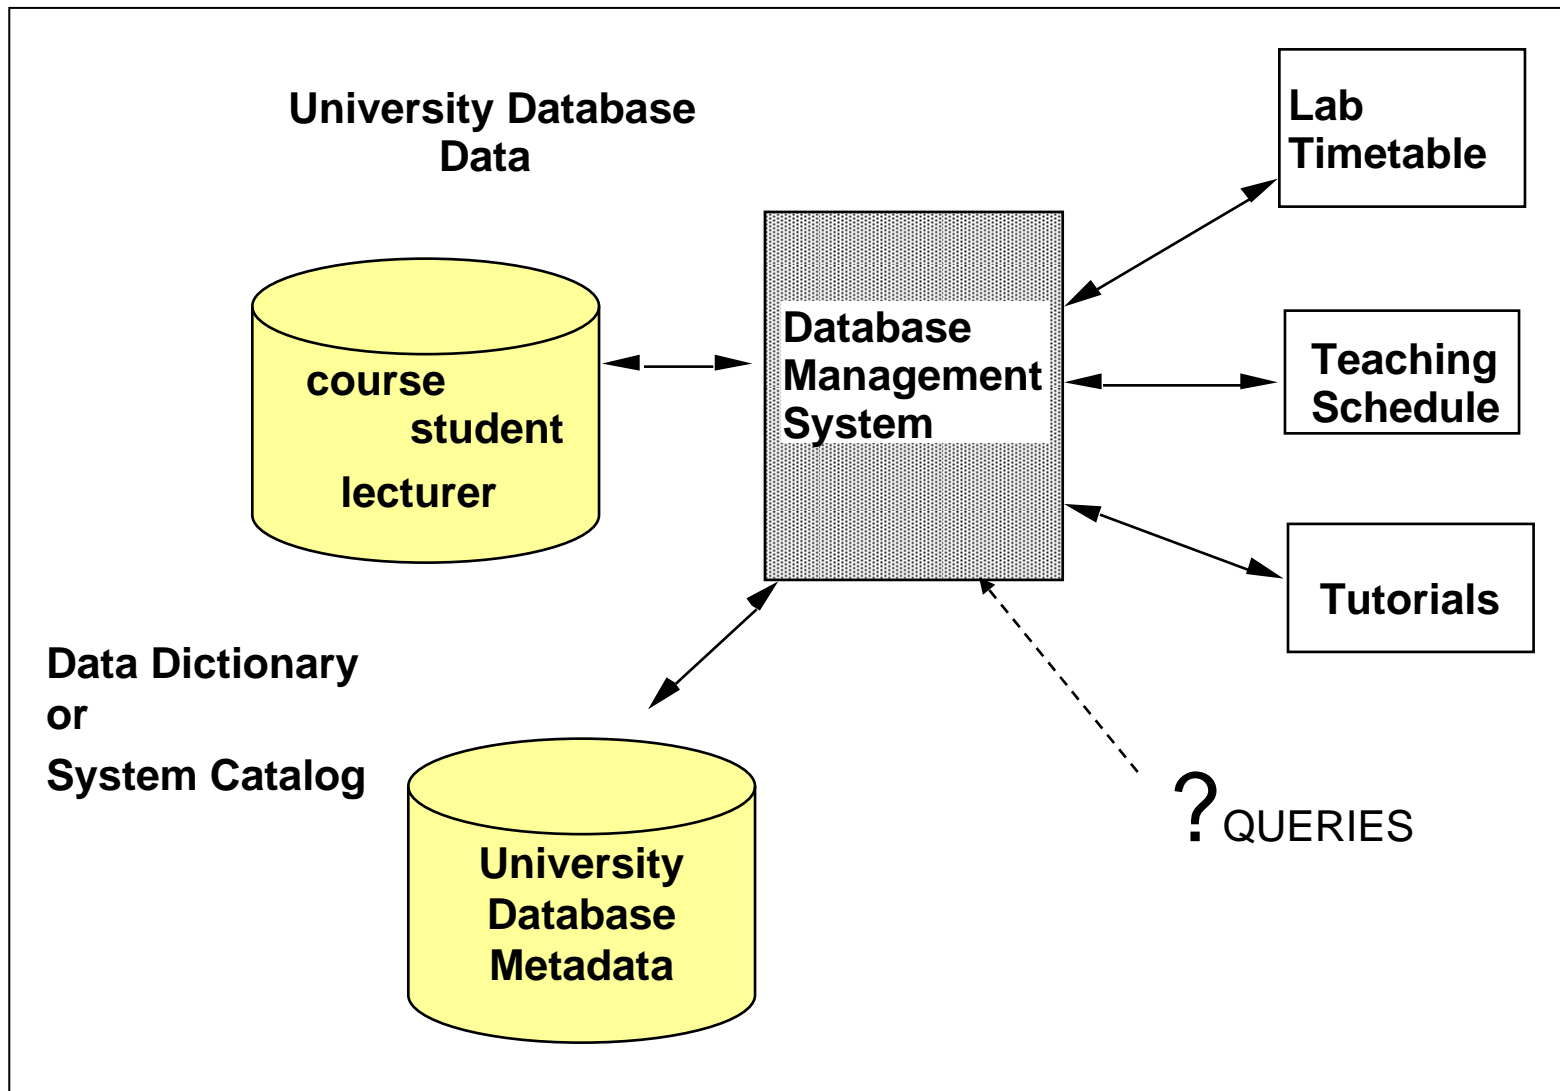

Sharing Data: Replication → Redundancy

Sharing Data and Operations

DBMS: A Logical Interface

File System Approach

- Uncontrolled redundancy
- Inconsistent data
- Inflexibility
- Limited data sharing
- Poor enforcement of standards
- Low programmer productivity
- Excessive program maintenance
- Excessive data maintenance

DBMS Approach

- **Controlled redundancy**
 - consistency of data & integrity constraints
- **Integration of data**
 - self-contained
 - represents semantics of application
- **Data and operation sharing**
 - multiple interfaces
- **Services & controls**
 - security & privacy controls
 - backup & recovery
 - enforcement of standards
- **Flexibility**
 - data independence
 - data accessibility
 - reduced program maintenance
- **Ease of application development**

However....

If an application is

- simple
- stringent real-time
- single user
- static,

files are the option of choice

DBMS downside:

- more expensive
- more complex
- general

Summary:

- In a **file system**, data is *physically accessed* and *not integrated*
- In a **DBMS**, data is *logically accessed* and *integrated*:
 - query language
 - data dictionary
