Agent Architectures and Hierarchical Control

Overview:

- Agents and Robots
- Agent systems and architectures
- Agent controllers
- Hierarchical controllers

A situated agent perceives, reasons, and acts in time in an environment.

- An agent is something that acts in the world.
- A purposive agent prefers some states of the world to other states, and acts to try to achieve worlds they prefer.
- Agents interact with the environment with a body.
- An embodied agent has a physical body.
- A robot is an artificial purposive embodied agent.

- Agents can have sensors and effectors to interact with the environment.
- Agents have (limited) memory and (limited) computational capabilities.
- Agents reason and act in time.

Agent Systems

A agent system is made up of a agent and an environment.

- An agent receives stimuli from the environment
- An agent carries out actions in the environment.

Agent System Architecture

- An agent interacts with the environment through its body.
- The body is made up of:
 - sensors that interpret stimuli
 - actuators that carry out actions
- The controller receives percepts from the body.
- The controller sends commands to the body.
- The body can also have reactions that are not controlled.

Implementing a controller

- A controller is the brains of the agent.
- Agents are situated in time, they receive sensory data in time, and do actions in time.
- The controller specifies the command at every time.
- The command at any time can depend on the current and previous percepts.

The Agent Functions

- Let T be the set of time points.
- A percept trace is a function from T into P, where P is the set of all possible percepts.
- A command trace is a function from *T* into *C*, where *C* is the set of all commands.
- A transduction is a function from percept traces into command traces.
- A transduction is causal if the command trace up to time t depends only on percepts up to t.
- A controller is an implementation of a causal transduction.

- A causal transduction specifies a function from an agent's history at time *t* into its action at time *t*.
- An agent doesn't have access to its entire history. It only has access to what it has remembered.
- The internal state or belief state of an agent at time *t* encodes all of the agent's history that it has access to.
- The belief state of an agent encapsulates the information about its past that it can use for current and future actions.

Functions implemented in a controller

For discrete time, a controller implements:

- belief state transition function remember(s, p), where s is a belief state and p is a percept, returns the next belief state.
- command function do(s, p), where s is a belief state and p is a percept, returns a command for the agent.
