

Running time (or time complexity) of a T.M.

A T.M. has time complexity $T(n)$ if it halts in at most $T(n)$ steps (accepting or not) for all input strings of length n .

Polynomial time: $T(n) = O(n^c)$ for some fixed c
(fixed means independent from n , i.e. the input-size)

Examples : $O(n^2)$

$O(n \cdot \lg n)$

$O(n^{3.14})$

$O(n^{\lg n})$

$O(2^n)$

$\left. \begin{array}{l} \\ \\ \\ \end{array} \right\}$ polynomial time

$\left. \begin{array}{l} \\ \\ \end{array} \right\}$ non-poly

Complexity theory considers tractable all problems with poly-time algorithms.

Motivations:

1) robustness wrt the computation model

(all general computation models can simulate each other in poly-time \Rightarrow they define the same class of tractable prob.)

2) robustness wrt combining algorithms

(e polynomial of e polynomial is still a polynomial)

3) jump from polynomial to non-polynomial is drastic also in practice (e.g. compare $10 \cdot n^4$ with $0.1 \cdot 2^n$; when n grows)

Li) Most practically used algorithms that are polynomial are so with a low coefficient (i.e. $T(n) = O(n^c)$, with c typically ≤ 3).

Time complexity classes:

Definition: $P = \{L \mid L = \mathcal{L}(M) \text{ for some poly-time DTM } M\}$

$NP = \{L \mid L = \mathcal{L}(N) \text{ for some poly-time NTM } N\}$

Note: both DTMs and NTMs must be halting T.M.s

From the definition we have immediately: $P \subseteq NP$
(every NTM is also a DTM)

Note: being in P corresponds to the intuition that the problem can be solved efficiently.

Instead, being in NP means intuitively that, given a solution, we can check efficiently whether it is correct.

Satisfiability:

Boolean formulae: operands: x_1, \dots, x_n

operators: \wedge, \vee, \neg

formula $F(x_1, \dots, x_n)$

Satisfiability problem: given a boolean formula $F(x_1, \dots, x_n)$, is there a truth assignment (i.e., an assignment of true/false values) for x_1, \dots, x_n that satisfies F (i.e., makes F evaluate to true)?

Example: $F(x_1, x_2) = (x_1 \vee \neg x_2) \wedge (\neg x_1 \vee x_2)$

(5.3)

is satisfiable: $x_1=1, x_2=1$

$$F(x_1, x_2) = x_1 \wedge (\neg x_1 \vee x_2) \wedge \neg x_2$$

is not satisfiable

We first show how we can convert it to a language problem:

- we must encode formulas as strings

$$\Sigma = \{\wedge, \vee, \neg, (,), x, 0, 1\}$$

variable $x_i: x^{(i\text{-in-binary})}$

e.g. x_5 is encoded as $x101$

\Rightarrow we obtain that $F(x_1, \dots, x_n)$ can be encoded as a string over Σ .

$$L_{SAT} = \{w \mid w \text{ encodes a satisfiable formula}\}$$

Theorem: $L_{SAT} \in NP$ (i.e., satisfiability is in NP)

Proof:

It suffices to show a poly-time NTM N s.t. $L(N) = L_{SAT}$

N runs in two steps:

1) "guess" a truth assignment F for x_1, \dots, x_n

2) evaluate F on truth assignment and whether it has value true.

We have: F satisfiable $\Leftrightarrow \exists$ satisfying T.A.

$\Leftrightarrow N$ has accepting execution

Running time: step 1) $O(n)$

step 2) $O(n^2)$ with multiple steps $\Rightarrow O(n^4)$ q.e.d.

Note :- All decision problems can be converted to language problems, by encoding the input as a string.

- We know that $L_{SAT} \in NP$, but we do not know whether L is in P.
- we cannot exploit the conversion $NTM \rightarrow DTM$, since it causes an exponential blowup in running-time
- under the standard $NTM - DTM$ conversion, the DTM will have to try all possible truth-assignments (2^{2n})

In fact : open whether $L_{SAT} \in P$

Special case of SAT: CSAT

conjunctive normal form:

(note: we use + for \vee

and \cdot for \wedge)

- literal : variable x_i or its negation \bar{x}_i

- clause : sum /or of literals : $C_j = x_1 + \bar{x}_2$

- CNF-formula: product/end of clauses : $F = C_1 \cdot \dots \cdot C_m$

$$\text{thus } F = \prod_{j=1}^m C_j \quad \text{with } C_j = \sum_{i=1}^{n_j} x_{ji}$$

CSAT - problem: given a CNF formula, F,
decide whether F is satisfiable

Since $SAT \in NP$, we have also $CSAT \in NP$

k -CNF-formule: each clause has exactly k literals

$$1\text{-SAT} : (\bar{x}_1) \cdot (\bar{x}_2) \cdot (\bar{x}_3)$$

$$2\text{-SAT} : (x_1 + \bar{x}_2) \cdot (\bar{x}_1 + x_2)$$

3-SAT :

Facts: 1-SAT $\in P$ (trivial)

2-SAT $\in P$ (not so easy - via graph reachability)

3-SAT $\in P$ is still open

There are many (thousands) problems like SAT and CSAT that can be easily established to be in NP as follows:

Step 1: "guess" some solution S

Step 2: verify that S is a correct solution

Note: Step 1 exploits nondeterminism, and is clearly polynomial (running time of a NTM)

Step 2, for the problem to be in NP, must be carried out deterministically in poly-time (polynomial verifiability)

Examples:

- Traveling salesman problem (TSP)

input: - graph $G = (V, E)$ with edge lengths $l(u, v)$
- integer k

problem: does G have a tour (visiting each node exactly once) of length $\leq k$?

TSP $\in NP$

Step 1: guess a tour

Step 2: check that length of tour is $\leq k$

- Clique : input - graph $G = (V, E)$
- integer k

problem: does the graph have a clique of size k
(\therefore clique is a subgraph of G in which each pair of nodes is connected by an edge)

- Knapsack : input : - set of items, each with an integer weight
- capacity k of a knapsack
- problem: is there a subset of the items whose total weight matches the capacity k

This property explains why so many practical problems are in NP:

- problems ask for the design of mathematical objects (paths, truth assignments, solutions of equations, VLSI-routes,...)
- sometimes we look for the best solution, (or a solution that matches some condition) that matches the specification
- the solution is of small (polynomial) size, otherwise it would be useless
- it is simple (poly-time) to check whether it matches the spec. but, there are exponentially many possible solutions

If we had $P = NP$, all these problems would have efficient (poly-time) solutions.

But we currently believe that $P \neq NP$.

Assuming $P \neq NP$, how do we determine which problems of NP are not in P (i.e., we know they don't have an efficient algorithm)?

NP-completeness

Key idea: we define NP-completeness in such a way that if we show that an NP-complete problem is in P, then all problems in NP would be in P.
(i.e., we would have $P = NP$)

It follows: assuming $P \neq NP$, an NP-complete problem cannot be in P

Poly-time reduction:

Problem X reduces to problem Y in poly-time ($X \leq_{\text{poly}} Y$) if there is a function R (the poly-time reduction) s.t.

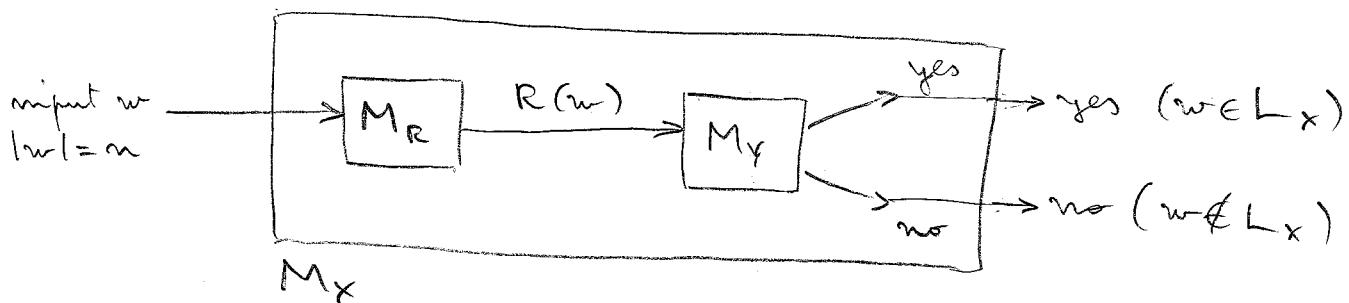

- 1) $w \in L_X \iff R(w) \in L_Y$
- 2) R is computable by a poly-time DTM
(L_X is the language encoding of problem X)

Theorem: $X \leq_{\text{poly}} Y$ and $Y \in P \Rightarrow X \in P$

Proof: let M_R be a poly-time DTM for R

$$M_Y \quad - \vdash - \quad Y$$

We construct a DTM M_X for X as follows

Running time of M_X :

Suppose: M_R runs in time $T_R(n) \leq n^a$

$$M_Y \quad - \vdash - \quad T_Y(n) \leq n^b$$

Let $|w| = n$

Then $|R(w)| \leq n^a$

$\Rightarrow M_X$ runs in time \dots

$$\begin{aligned} T_X(n) &\leq T_R(n) + T_Y(T_R(n)) = \\ &= n^e + (n^a)^b = O(n^{e+b}) \end{aligned}$$

q.e.d.

Corollary: $X \leq_{\text{poly}} Y$ and $X \notin P \Rightarrow Y \notin P$

Definition: Problem Y (or language L_Y) is NP-hard if

$\forall X \in \text{NP}$ we have $X \leq_{\text{poly}} Y$

Intuitively: an NP-hard problem is at least as hard as any problem in NP

Immediate: Y is NP-hard and $Y \in P \Rightarrow P = \text{NP}$

Definition: Y is NP-complete if

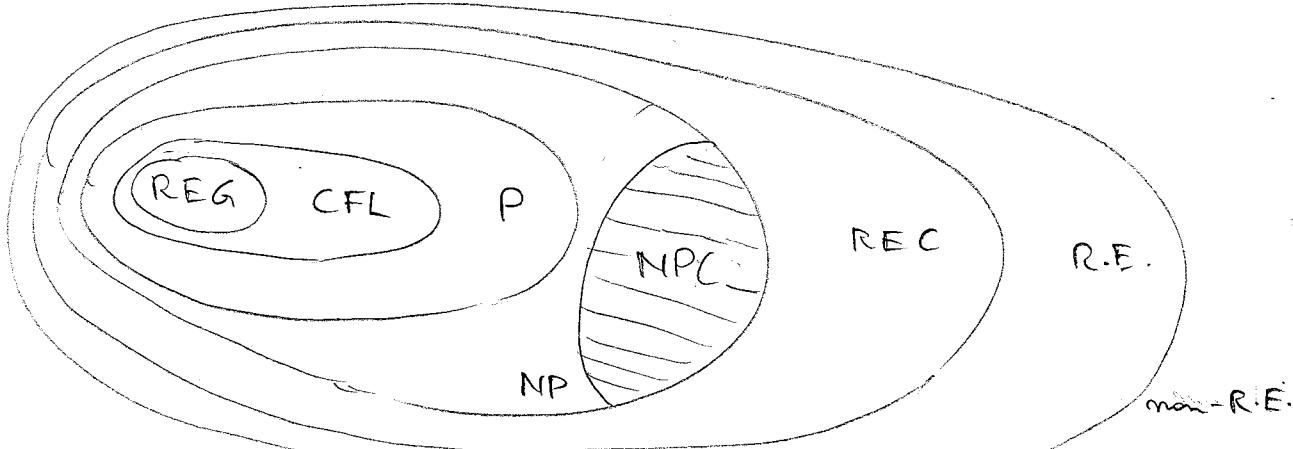

- 1) $Y \in \text{NP}$ and
- 2) Y is NP-hard

Intuitively: NP-complete problems are the hardest problems in NP.

If one of them is in P, then all problems in NP are in P.

Hence = NP-completeness is a strong evidence of intractability.

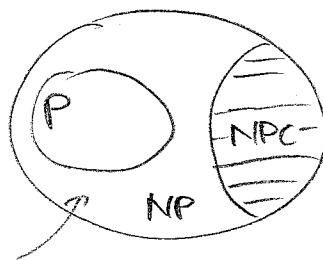

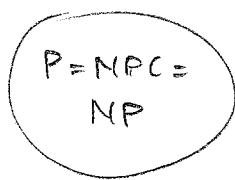

languages:

Note: relationship between P, NPC, and NP

5.8

either $P = NP$ or $P \neq NP$

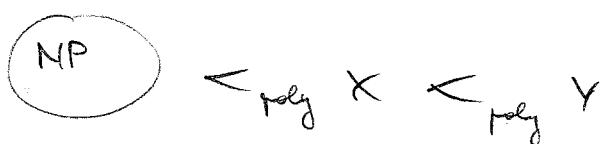

in this case we know there are problems in NP that are neither in P nor NPC
(proof is complicated)

How do we prove problems to be NP-complete?

Theorem: X is NP-hard and $X \leq_{\text{poly}} Y \Rightarrow Y$ is NP-hard

Proof:

But, to exploit this result, we need a first NP-hard problem:

Cook's theorem: CSAT is NP-hard

2/12/2008

Proof idea: we must show: $\forall L \in NP : L \leq_{\text{poly}} L_{\text{CSAT}}$

Fix $L \in NP$ and let M_L be a poly-time NTM for L .

We must show a poly-time reduction R_L :

input: string w

output: CNF formula $F = R_L(w)$ s.t.

$w \in L(M_L) \Leftrightarrow F$ is satisfiable

Idea: F encodes the computation of M_L on w .

Suppose $w \in L(M_L)$ and $|w| = n$.

then there exists a sequence of IDs of M_L :

$$ID_0 \vdash ID_1 \vdash \dots \vdash ID_T$$

with

$$ID_0 = q_0 w$$

ID_T is an accepting ID (i.e. M_L is in an

$T \leq P(n)$ (since M_L is poly-time) final state.)

We assume that $T = P(n)$ by adding

$$ID_{T+1}, ID_{T+2}, \dots, ID_{P(n)} \text{ same as } ID_T$$

Idea: encode computation as matrix X

TAPE \rightarrow

TIME ↓	1	2	3	n n+1 n+2			P(n)	$w = a_1 \dots a_n$		
	0	a_1/a_2	a_2/a_3	\dots	a_m	b	b	\dots	b	b
1	b_1	a_1/a_2	a_3	\dots	a_m	b	b	\dots	b	b
2	b_1	b_2	a_3/a_4	\dots	a_m	b	b	\dots	b	b
\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots
$P(n)$	b_1	b_2	b_3	\dots	b_n	c_1/c_2	c_2	\dots	c_1	b_2

M cannot use more than $P(n)$ cells

x_{it} : contents of tape cell i in ID_T

except for composite symbol

to denote state and head position

We have that $w \in L(M_L)$ iff

a) the matrix X is properly filled in

b) row 0 is ID_0

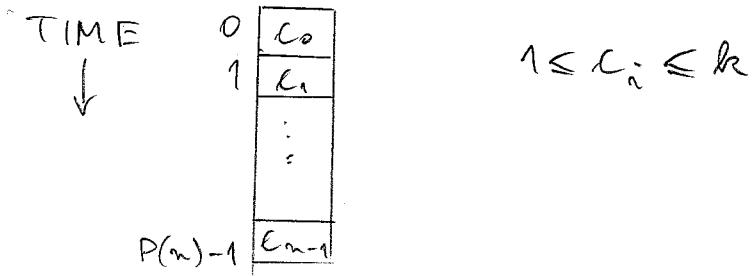

c) row $P(n)$ has final state

d) successive rows are related through legal transitions of M_L

M_L is NTM. Let k be the maximum degree of nondeterminism, i.e., for all $q, x : |\delta(q, x)| \leq k$.

To encode which of the possible transitions is chosen when going from ID_i to ID_{i+1} for the accepting sequence:

We use an array C of $P(n)$ elements (close array)

To represent X and C we use boolean variables

$x_{ita} = \text{true if cell } i \text{ in } ID_t \text{ contains } A$

$c_{tl} = \text{true if } c_t = l$

where $1 \leq i \leq P(n)$

$0 \leq t \leq P(n)$

$A \in \Gamma' = \Gamma \cup \underbrace{\Gamma \times Q}$

composite symbols

$1 \leq l \leq k$

Total number of variables is $O(P(n)^2)$, i.e., polynomial

To construct the CNF formula F , we use 4 types of formulas
 type e) X and C are properly filled in; (that are conjunctions of clauses)

UNIQUE(i, t): for each i and t , cell i in ID_t is uniquely filled

$$\left(\sum_{A \in \Gamma'} x_{ita} \right) \cdot \pi_{A; B \in \Gamma'} \left(\overline{x_{ita}} + \overline{x_{itb}} \right)_{A \neq B}$$

UNIQUEC(t) : for each t , $C[t]$ is uniquely filled (5.12)

$$\left(\sum_{\ell \in \{1, \dots, h\}} C_{t,\ell} \right) \cdot \prod_{\substack{\ell_m \in \{1, \dots, h\} \\ \ell \neq \ell_m}} \left(\overline{C}_{t,\ell} + \overline{C}_{t,\ell_m} \right)$$

$\Rightarrow O(P(n)^2)$ clauses, which is still polynomial
(since $1 \leq i \leq P(n)$ and $0 \leq t \leq P(n)$)

Each clause has constant length (i.e., independent of m).

Type b) $ID_0 = q_0 w = q_0 a_1 \dots a_m$

INIT: $x_{1,0} \boxed{q_0 a_1} \cdot x_{2,a_1} \cdots x_{m,a_m}$

$x_{n+1,0} \not\models \cdot x_{n+2,0} \not\models \cdots x_{P(n),0} \not\models$

$\Rightarrow O(P(n))$ clauses, each of length 1

Type c) $ID_{P(n)}$ is accepting

ACCEPT: $\sum_{\substack{q \in F \\ A \in \Gamma \\ i \in \{1, \dots, P(n)\}}} x_{i,P(n), \boxed{q A}}$

$\Rightarrow 1$ clause of length $O(P(n))$

Type d) legal transitions

consider ID_t and ID_{t+1}

t	$A_1 A_2 \dots \cancel{A_j} A_{j+1} \dots $	t
$t+1$	$B_1 B_2 \dots B_j \cancel{A_{j+1}} \dots $	t

In ID_{t+1} , cell j depends only on 3 cells above it and on A_t

A_{j+1}	A_j	A_{j-1}
B_j		

Various cases: (we assume that there are no stay moves)

1) A_{j-1}, A_j, A_{j+1} are not composite symbols

$$\text{then } B_j = A_j$$

2) A_{j-1} is $\begin{array}{|c|} \hline q \\ \hline x \\ \hline \end{array}$ and t 'th move in $S(q, x)$ is (γ, Y, R)

$$\text{then } B_j = \begin{array}{|c|} \hline \gamma \\ \hline A_j \\ \hline \end{array}$$

3) A_j is $\begin{array}{|c|} \hline q \\ \hline x \\ \hline \end{array}$ and t 'th move in $S(q, x)$ is $(\gamma, Y, -)$

$$\text{then } B_j = Y$$

4) A_{j+1} is $\begin{array}{|c|} \hline q \\ \hline x \\ \hline \end{array}$ and t 'th move in $S(q, x)$ is (γ, Y, L)

$$\text{then } B_j = \begin{array}{|c|} \hline \gamma \\ \hline A_j \\ \hline \end{array}$$

We use clauses that forbid illegal moves: $\text{LEGAL}(t, j)$

$$\begin{array}{l} \pi \\ D, E, F, G, H \\ \text{s.t. with clause } D \\ \text{and } \begin{array}{|c|} \hline E \\ \hline F \\ \hline G \\ \hline H \\ \hline \end{array} \text{ we} \\ \text{there are } \underline{\text{illegal}} \text{ moves} \end{array} \left(\begin{array}{l} \bar{x}_{t,D} + \bar{x}_{j-1,t,E} + \bar{x}_{j,t,F} + \bar{x}_{j+1,t,G} \\ + \bar{x}_{j,t+1,H} \end{array} \right)$$

(N.B. the illegal moves are those that do not correspond to 1-4 above)

$\Rightarrow O(P(n)^2)$ clauses, each of constant length
(since $0 \leq t < P(n)$, $1 \leq j \leq P(n)$)

Formula F is the conjunction of all above clauses.

We can prove that $w \in L(M_1)$ iff F is satisfiable.

It is easy to see that the reduction is poly-time q.e.d.

For a collection of NP-complete problems with discussion of variants see

Garey & Johnson.

Computers and Intractability. A guide to the Theory of NP-completeness

Frederick P. Greenbaum & Co. 1973

12/12/2007

2/12/2008

coNP = completeness

Let us consider the complement of a problem in NP.

E.g. unsatisfiability

$\text{UNSAT} = \{ F \mid F \text{ is a propositional formula that is not satisfiable} \}$

Given a prop. formula F , how can we check whether $F \in \text{UNSAT}$?

- try all possible truth assignments for the vars in F
- if for none of these, F evaluates to true, answer yes

Intuitively, this is very different from a problem in NP.

Note: in general, a NTM cannot answer yes to such a problem in polynomial time

Definition: $\text{coNP} = \{ L \mid \bar{L} = \Sigma^* \setminus L \in \text{NP} \}$

Note: many problems in coNP do not seem to be in NP.

We might conjecture $NP \neq coNP$

5.15

This conjecture is stronger than $P \neq NP$.

- indeed, since $P = coP$, we have that $NP \neq coNP$ implies $P \neq NP$

- but we might have $P \neq NP$, and still $NP = coNP$

The following result shows a strong connection between NP-complete problems and the conjecture that $NP \neq coNP$.

Theorem: If for some NP-complete problem/language L we have $\bar{L} \in NP$ (i.e., $\bar{L} \in coNP$), then $NP = coNP$.

Proof: Assume $L \in NPC$ and $\bar{L} \in NP$.

1) We show $NP \subseteq coNP$:

Let $L' \in NP$. We show $L' \in coNP$, i.e. $\bar{L}' \in NP$.

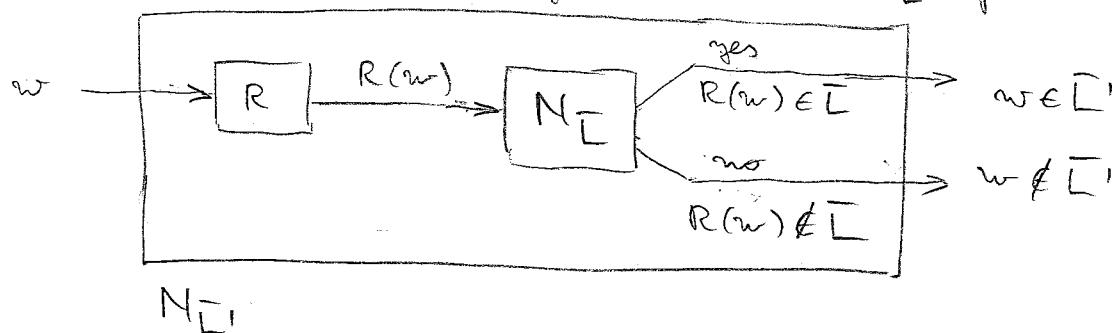

Since $\bar{L} \in NP$, there is a poly-time NTM $N_{\bar{L}}$ s.t. $\bar{L}(N_{\bar{L}}) = \bar{L}$.

Since $L' \in NP$ and $L \in NPC$, $L' \leq_{poly} L$, i.e.

(there is a polytime reduction R s.t.

$$\begin{aligned} w \in L' &\iff R(w) \in L \quad \text{i.e.} \\ w \in \bar{L}' &\iff R(w) \in \bar{L} \end{aligned}$$

We can construct a poly-time NTM $N_{\bar{L}'}$ for \bar{L}'

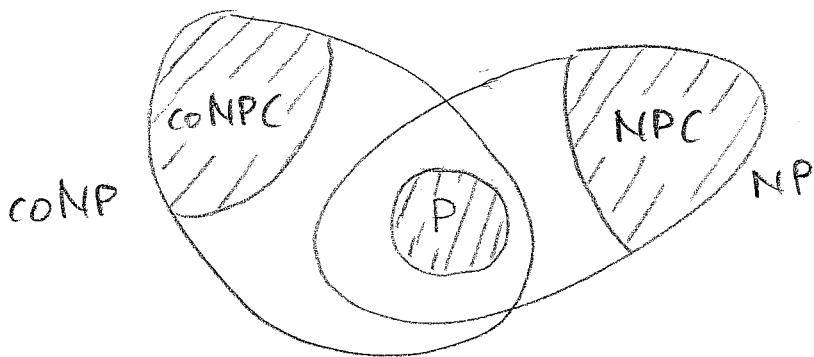

2) $coNP \subseteq NP$. Similar

q.e.d.

We get the following picture (assuming $P \neq NP$
 $NP \neq coNP$)

(5.16)

Note: it is not known whether $P = NP \cap coNP$

Exercise: Let $G = (V, E)$ be an undirected graph 5.17

A vertex cover C of G is a subset of the vertices V s.t. every edge of G touches at least one of the nodes of C .

The vertex cover problem:

input: - graph $G = (V, E)$
- integer k

output: yes iff G has a vertex cover of size $\leq k$

Vertex-cover is NP-complete:

Proof:

in NP: easy

- guess a subset C of V of size $\leq k$
- check in poly-time that it is a vertex-cover

NP-hard by reduction from 3-SAT

We define a poly-time reduction R that:

- takes as input a 3-CNF formula F
- constructs a graph $G = (V, E)$ and an integer k such that:

F is satisfiable $\Leftrightarrow G$ admits a vertex cover with k nodes

Let $F = C_1 \cdot \dots \cdot C_m$ be a 3-CNF formula over variables $\{x_1, \dots, x_n\}$

We construct $G = (V, E)$ as constituted by various components

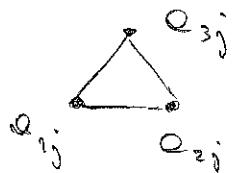

- For each variable x_i , we have a truth-setting component $T_i = (V_i, E_i)$ with $V_i = \{x_i, \bar{x}_i\}$

$$E_i = \{\{x_i, \bar{x}_i\}\}$$

undirected edge

note: at least one of x_i, \bar{x}_i will be in every vertex cover to cover $\{x_i, \bar{x}_i\}$

- For each clause C_j with we have a satisfaction testing component $S_j = (V'_j, E'_j)$

note: at least two of V'_j will be in every vertex cover to cover E'_j

- We have a communication component, which is the only part that depends on which literals are in which clauses

$$\text{let } C_j = l_{1j} + l_{2j} + l_{3j}$$

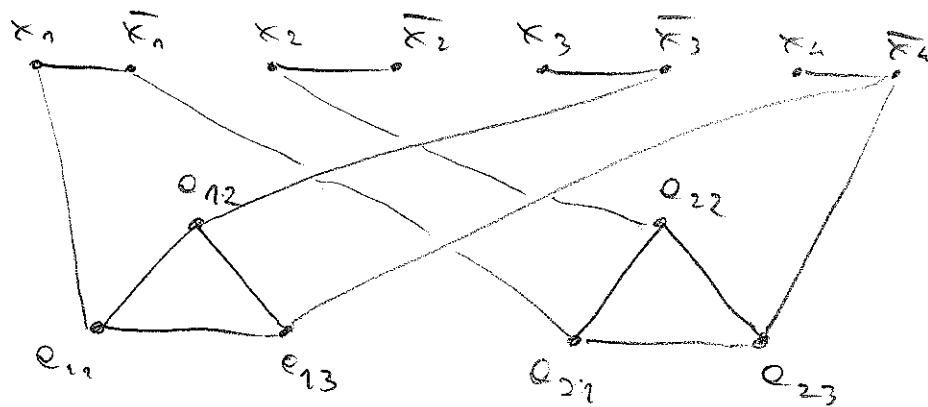

$$\text{Then we have } E'_j = \{\{e_{1j}, l_{1j}\}, \{e_{2j}, l_{2j}\}, \{e_{3j}, l_{3j}\}\}$$

We then set $K = m + 2m$

\uparrow # variables \uparrow # clauses

Example : $F = (x_1 + \bar{x}_3 + \bar{x}_4) \cdot (\bar{x}_1 + x_2 + \bar{x}_4)$

5.19

$$h = m + 2n = 4 + 2 \cdot 2 = 8$$

We show that F is satisfiable $\Leftrightarrow G$ has a vertex cover of size $\leq h$

" \Leftarrow " Let $V' \subseteq V$ be a vertex cover for G with $|V'| \leq h$.
 We said that V contains - one vertex for each vehicle
 at least - 2 vertices for each clause

This is already $h = m + 2n$

\Rightarrow at least is actually exactly

We use V' to obtain the truth assignment γ

we set $x_i = \text{true}$ if $x_i \in V'$

$x_i = \text{false}$ if $x_i \notin V'$

To show that γ is a truth assignment that satisfies F , we exploit that all edges of the communication components are covered by V' :

Consider a clause $C_j = l_{1j} + l_{2j} + l_{3j}$

- two of the edges in E_j are covered by the choice of two edges $e_{ij}, e_{2j}, e_{3j} \in V'$

W.l.o.g., let there be e_{1j}, e_{2j}

- the third arc is then covered by the literal l_{3j} (connected to e_{3j}) which has to be in V' .

Since, by definition of γ , $l_{3j} = \text{true}$, C_j is satisfied.

" \Rightarrow " Let γ be a truth assignment that satisfies F .

We define a subset $V' \subseteq V$ as follows

- $x_i \in V'$ iff $\gamma(x_i) = \text{true}$

$\bar{x}_i \in V'$ iff $\gamma(x_i) = \text{false}$

Since γ satisfies F , for each communication component

$$E_j'' = \{e_{1j}, l_{1j}\}, \{e_{2j}, l_{2j}\}, \{e_{3j}, l_{3j}\},$$

one of the three edges $\{e_{ij}, l_{ij}\}$ is covered in V' by l_{ij} .
W.l.o.g., let $i=1$. Then $\{e_{2j}, l_{2j}\}, \{e_{3j}, l_{3j}\}$ can
be covered by having $e_{1j} \in V'$ and $e_{3j} \in V'$.

We get that V' contains $n+2m$ vertices.
